The treatment of the disease is presented in an interesting style and the various modern methods of therapy are referred to and often commented on. Serum therapy is treated at length and mention is made of the anti-polio-myelitic horse serum and of the dangerous and even fatal reactions following its use. One is again impressed with the necessity of caution in the distribution and use of new serums or vaccines until experimental study has established their reasonable safety when used in a prescribed manner. One is also startled to hear of the proposal and use of cisternal puncture in poliomyelitis patients. It is a relief to know that the authors consider the latter measure contra-indicated and the anti-polio-myelitic horse serum too dangerous to use. In comparison with the latter serum, convalescent serum is a harmless remedy certainly by the intramuscular route. The intraspinal injection, however, of this human serum is accompanied by severe reactions which make it hazardous notably in patients with bulbar symptoms.

Chapter thirteen on "After Care of Paralysis" is well presented, the opinions expressed are sound, logical and well balanced. Measures of physiotherapy might perhaps receive a somewhat more important place than that given to them.

JOSEPH C. REGAN

The Autonomic Nervous System. By Albert Kuntz, M.D. Second edition. Octavo of 697 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$7.50.

This work of which this is the second edition, is a classic in its field. It is the reference book, *sine qua non*, in the study of the autonomic nervous system. In the analysis of problems relative to the autonomic nervous system, requiring a perusal of the related literature, a careful survey always begins with and sometimes ends with this particular book. There is a vast amount of literature being produced on this subject, so huge indeed, that without a work of this

type in which the essentials are carefully sifted the uninitiated would soon be foundering. Its 125 pages devoted solely to references to the literature bear witness to the patience, care, and zeal of the author.

The general plan of the first volume has been followed in this edition. So many changes have taken place, particularly in the treatment of disease and in clinical investigation that the book has been really written anew. We find a thorough consideration of the anatomy and physiology, the relationship to individual organs or tissues, the action of the autonomic nervous system in disease, its bearing on referred pain, and finally the present surgical considerations.

It is so detailed, so accurate, and so thoroughly complete that the connotation of "A Bible on Autonomic Nervous Disease" would be fitting. It is so generally accepted as an authoritative reference work, that the reviewer in indorsing it, is following the crowd.

HAROLD R. MERWARTH

Tuberculosis in the Child and the Adult. By Francis M. Pottenger, M.D. Octavo of 611 pages, illustrated. St. Louis, C. V. Mosby Company, 1934. Cloth, \$8.50.

This new work by a most able authority with vast experience in his field offers to the physician and student a clear insight into many of the problems encountered in pulmonary tuberculosis. It is well written and illustrated with many case reports and x-ray pictures. The chapter on visceral neurology in pulmonary tuberculosis is excellent as are the chapters dealing with therapy. There is some vagueness in the chapters dealing with infection and immunity, but on the whole it is a worthy addition to the works on pulmonary tuberculosis.

CHARLES E. HAMILTON

Aids to Osteology. By Philip Turner, F.R.C.S. Third edition. 16mo. of 222 pages. Baltimore, William Wood & Company, 1934. Cloth, \$1.50.

This book is a pocket-size edition containing 222 pages of names and concise descriptions in osteology, with a complete index. In this new edition the author employs an approved English terminology, a desirable feature which one may find very helpful to eliminate confusion and hardship in memorizing when written in Latin. Although a small book, it is comprehensive and will prove most valuable to the student for study and review of osteology, and to the practitioner and surgeon in refreshing his knowledge of the regional bony anatomy.

JACOB S. BEILLY

INDUSTRIAL DERMATOSES**Causes, Prevention, and Treatment**

JOSEPH J. ELLER, M.D., *New York City*, and
LOUIS SCHWARTZ, M.D., *U. S. Public Health Service, New York City*

Industrial dermatoses constitute 60 per cent of the industrial diseases, not including actual accidents. The figures gathered from the states of Ohio, Missouri, Connecticut, New York, Massachusetts and Wisconsin show that among 15,050 industrial diseases recorded in these states over a period of years, 9,628 were dermatoses. In these states there was an average of 2,944 cases of occupational dermatitis yearly. By comparing the population of the above states with that of all the states we can safely estimate that there occurs yearly in the United States at least 12,000 cases of occupational dermatitis of sufficient severity to be reported. (See Table I.)

In 1934 New York State alone had 1,012 cases of occupational diseases, with 689 cases of compensated dermatoses. These dermatoses were largely made up of dermatitis venenata and dermatitis eczematosa. Included were a few cases of glanders, tuberculosis, anthrax, actinomycosis, sporotrichosis, erysipeloid, keratoses, cancers, calluses, burns, and abrasions.

Employees with milder dermatoses or afraid of losing their positions because of their hypersensitivity to the materials with which they worked, or because of prospective financial loss while being carried as compensation cases, often continued at their occupations. On the other hand, a larger number claimed compensation for trivial or unconnected dermatoses when fear of a lay off or earnings less than compensation rates seemed imminent. This last group includes some

malingeringers who actually produce dermatoses or who manage to prolong and maintain them in a variety of ways.

From the examination of many thousands of workers in various industries we can safely say that more than one per cent of the workers engaged in basic industries suffer some time during the year with an occupational dermatitis. These cases in general do not go to free clinics, but to private physicians. In a study of the number of trade dermatitis consultations in a published bulletin of a New York Hospital for the years from 1928 to 1933 inclusive, we find only 138 in over 600,000 consultations, i.e., less than one in every five to six thousand. We do not question that a much larger number were seen and catalogued as dermatitis venenata or eczemas. Certainly in clinic work a segregation of these cases with their special problems is indicated. We must agree with C. Guy Lane¹ that a more accurate and generally accepted classification of these diseases would be of great aid in their study. Over 10% of the cases of dermatitis venenata and eczema upon better analysis and classification would be occupational in origin. It must be realized that a large percentage of dermatitis cases found in industrial workers is due to the worker's contacts outside of his occupation.²

Causes

We must still be uncertain as to the part played by variations in pigmentation and age in the matter of predisposition.

Read at the Annual Meeting of the American Dermatological Association, White Sulphur Springs, Pa., May 1935

Blondes, the relatively young, and the aged are perhaps more susceptible to skin irritants. Unusually dry or moist skins are certainly predisposing factors. Thick and oily skins are undoubtedly more resistant.

Diseased and abnormal skins are more susceptible. Seborrhea, ichthyosis, pyogenic infections both focal and local, and individuals with skin injured from any cause offer less resistance to a skin irritant. A history of recurrent skin eruptions is always an indication of the possibility of skin sensitivity which increases chances of dermatitis. After sensitivity develops to one agent, the worker tends to be more sensitive to other substances.³

Fungus infections in their wide prevalence force us to consider their effect. They rank first in the group of other causes discussed above as injuring the skin. Secondly, with their induction of "phytids" they set up a sensitizing mechanism with a tendency to become polyvalent.⁴

Heavy metal poisoning (lead, arsenic, nickel, etc.) may possibly act as a predisposing agency, but this hypothesis is as yet unproven. Spectroscopic and other forms of skin analysis show varying metal contents in the skin of patients with dermatoses, but the same is frequently true in the majority of normal individuals and in those with other dermatoses.

Finally, the rough, ignorant, careless and slovenly person with poor hygiene, who does not keep his skin clean, and who is careless about clean clothes, is a menace to himself by providing the element of increased exposure, both temporal and quantitative, to the multitude of irritants about him. The individual with hay fever, asthma, and other manifestations of non-cutaneous allergy does not appear to be predisposed to occupational dermatitis according to our own observations.

The chief causes of industrial dermatitis differ in various localities according to the prevailing types of industry. In rural communities plant poisonings are prevalent. In Missouri, out of over 1,020 cases of industrial dermatitis, 69 per cent were due to lime and cement; 15 per cent due to poison ivy; 9 per cent to caustics and acids; 6 per cent to lye and 2 per cent to petroleum products. In Califor-

nia, the fruit business is the most important. In New York State (1933), of 489 cases of occupational dermatitis, 50 per cent were due to plants, 12 per cent to soaps and washing powders, 6 per cent to dyes, 3 per cent to turpentine, and 2 per cent to petroleum products, the remaining cases being due to a wide variety of causes. In 1934, New York State had 1,012 occupational disease claims disposed of, in which process 439 were allowed and 573 were disallowed. Table II shows the reasons for disallowance in 56.4 per cent of the cases of occupational poisoning and disease.

Table III by the Division of Industrial Hygiene from the New York State Department of Labor is instructive.

It can be safely stated that in general the majority of industrial skin diseases in the United States is caused by the

TABLE I.—REPORTED FREQUENCY OF OCCURRENCE

State	Year	Occupational Diseases	Dermatoses
California1933	1,528	1,156

	Petroleum distillates

The action on the skin of these various causes may be classified as follows:

1. *Keratin and Fat Solvents*, such as mild alkalis, soaps, turpentine and vegetable oils.

2. *Desiccators*, or hygroscopic agents, which take the water out of the skin, such as sulphuric acid and powerful alkalis.

3. *Protein Precipitants*, which form albuminates in combining with the skin. Heavy metal salts act in this manner.

4. *Oxidizers*, such as chlorine gas, peroxide of hydrogen, chromic acid and its salts.

5. *There is a group which tends to hydrolize* when coming in contact with the moisture of the skin, thus forming irritating compounds. Hexamethylenetetramine, for example, on hydrolizing forms formaldehyde and formic acid.

6. *Certain substances act as stimulants or irritants to the keratin forming cells of the skin* and are apt to cause new growth. Arsenic, petroleum products and anilin are substances of this kind.

7. *Then there is another group which is composed of sensitizers*. The nitro and the nitroso compounds act in this manner. The group is a very large one.

While it is certainly true that many cases of dermatitis develop only after years of exposure, most cases occur promptly in new workers or in employees exposed to new sensitizers. There is a definite epidemiology which appears in the exposure of individuals to a new irritant. Where to draw the line between irritants and sensitizers is often very difficult in classification. Dinitro-chlorobenzol in strong solution will irritate any skin. Individuals who become sensitized to it in some cases cannot enter a building in which it is in use without developing a facial erythema.⁵ However, a $\frac{1}{2}$ to 1 per cent solution may be used of this same chemical to patch test normal individuals who will show a negative test after 24 hours.

A demonstration of a strongly sensitizing varnish occurred in an outbreak of dermatitis among nineteen out of thirty-two exposed employees in two cotton mills. The latent period was from three days to four weeks of contact before the dermatitis appeared. The more severe cases appeared earlier. Twelve out of thirteen cases who developed a dermatitis were examined and had positive patch tests for the varnish. Five non-exposed individuals had negative patch tests. Re-

covery in these patients took from a few days to thirteen weeks.⁶

One point not generally considered is the apparent immunity which develops in workers after first being sensitive to materials they employ. It seems that this occurs in those who develop a mild dermatitis only. The workers themselves say that they "become hardened" to the agent. Unfortunately, this immunity lasts only from one week to a month, and on the resumption of work, the "immunizing" process must be repeated.

There is another kind of worker who works for many years without any trouble and then for some unknown reason becomes sensitized and develops a dermatitis from the materials which he previously handled with safety. Immunity does not develop in this type of sensitivity. They tend to develop hypersensitivity to other substances, and present a very difficult problem.

Symptoms and Course

When the average patient is first affected with itching and burning and the visible signs of an occupational dermatitis, and he presents himself for examination, his clinical appearance, excepting in a few cases, does not offer a clue to the irritant. Of course, burns by strong acids and caustics can be readily distinguished, and the primary action of fat solvents which cause the skin to become dry, and the dehydrators which give the skin a scaly, parchment-life appearance, can also be recognized. But it can be said that occupational dermatitis in its acute form is a dermatitis venenata and does not have an appearance which characterizes the specific irritant. It can be stated that erythema, edema, papules and vesicles of the exposed parts are characteristic of dermatitis due to external irritants. By the exposed parts, the parts exposed to the eye are not always meant, because the covered parts of the body may also be exposed to the action of penetrating dusts, fumes and liquids. When dust is the irritant, it is well to remember that the belt line, the ankle, and areas exposed to friction are often involved, especially the back of the neck. Table VIII attempts a simple outline of clinical types.

It is characteristic of a typical case of occupational dermatitis that it appears a

short time after the person is exposed to the offending material and that it tends to disappear after exposure has ceased; that is, it will get well if the person stops work for a length of time. It even becomes improved during the week-end holiday. It will reappear upon exposure to the irritant. We think that the best proof that a dermatitis from which the person is suffering is due to his occupation is that it appears when the man goes to work, gets well when the man stops work, and reappears when he goes back to work. This, of course, is the usual picture, but it is not always encountered. Some workers have alternating remissions and exacerbations while at work. These cases are difficult to explain. It may be possible that the conditions under which they work are not always the same. The dermatitis itself may exhibit a periodicity due to variations in the resistance of the persons or variations in his sensitivity. Focal infections and diet may be contributing factors. There is still another group of cases in which the primary dermatitis is followed by frequent relapses and finally by a chronic eczema, even after giving up employment. Infections with pus organisms and molds may also occur on top of occupational dermatoses and complicate the picture of the disease. It is very often difficult in such cases to prove that the occupation and not the complication was the original disease.

Diagnosis

The differential diagnosis from skin diseases due to other causes may be most

difficult. Rhus dermatitis and other simple conditions are continually confused with occupational dermatoses. The effects of irritating salves may mask the true picture. A detailed and pertinent history is important. In a recent report of a hundred cases presenting themselves for compensation only 18 were found in which the occupation was the proven cause.⁷ In 42 cases of this group dermatophytosis was the diagnosis. The others had a wide variety of dermatoses.

Industrial dermatitis itself cannot be differentiated by its appearance from other venenata or contact eczemas caused

Fig. 3 A "dust dermatitis" due to a synthetic intermediate dye occurring in a worker in drying ovens.

by like noxae in the patient's home and from outside sources.

In the matter of dermatophytids in the present state of our knowledge, inspection alone cannot always be relied on to differentiate them from eczemas of the contact type.⁸ Mycological examination of the suspected primary focus and of the "phytids" and culturing of material is usually necessary. Trichophyton and oidium mycin intracutaneous tests may aid in diagnosis. Patch tests should be done, but finally a personal evaluation of each case is necessary. The fungus infection often coexists with the dermatitis. One predisposes the individual to the other and vice versa. Over three times as many fungus infections in employees of a hat factory were found in those engaged in wet processes as in those working at dry

TABLE VIII.—CLINICAL TYPES

Acute dermatitis venenata or eczematosa . . .	characterized by erythema, edema, papules, vesicles, exudation, crusts, and finally desquamation—usually the result of general and specific irritants.
Chronic fissured Eczemas	characterized by erythema, lichenification, cornification, fissuring—usually the result of dehydrators, fat solvents, soaps and detergents.
Folliculitis and acne	characterized by plugged sebaceous follicles and suppurative lesions—usually caused by oils, waxes and chlorine.
Epidermal proliferation, . . . (Benign and malignant)	characterized by keratosis, papillomata and epitheliomata of exposed parts—usually caused by petroleum, coal tar and derivatives, arsenic and anilin.

processes." Certain industrial conditions undoubtedly tend to influence the number and severity of fungus infections.

The patch test in contact dermatoses may be of diagnostic importance but cannot always be relied upon. It is much superior to the intradermal and scratch tests in this field. The individual's reaction to an irritant by the patch test varies with the degree of sensitization, the strength of the concentration, the actual quantity of the substance applied to a given area of skin, and the duration of the application. Needless to say, care must be exercised in the application of tests. A concentrated general irritant will give positive patch tests on all skins, and on a sensitized individual it will cause actual necrosis. With an unknown or new irritant a question as to whether fellow workers can handle the material with impunity may help one decide whether to patch test without diluting. Dry substances should be moistened with water. Table IX shows Rudolph Mayer's list of substances and concentrations which on healthy, normal skins cause no reaction in twenty-four hours by patch test.

Another list of irritants which can be used follows:

Di nitro chlor benzol.....0.5% alcoholic solution
Amino azo toluene.....2% alcoholic solution
Beta naphthol.....20% in olive oil
Di ortho tolyl guanidine.....Pure powder
Di ortho tolyl thiourea.....Ditto
Mono benzyl para amino phenol.....Pure
Meta toluyluene diamine.....Ditto
Michler's Hydrol.....5% alcoholic solution
Naphthylamine.....2% alcoholic solution
Nitroso di ethyl anilin...1% alcoholic solution
Phenyl alpha naphthylamine.....Pure
Platamine black.....Solid powder
Para nitro benzoic acid.....Pure
Phenylglycine.....Ditto
Tetra methyl thiuram mono sulphide.....Ditto
Tetra methyl thiuram di sulphide.....Ditto

A much larger list of this sort will be reported during the present year. Although the patch test may be negative at the end of twenty-four hours, any erythema or other process developing at the site in the next few days still makes the test positive and indicates hypersensitivity.

The failures of the patch test and the sources of false positives or negatives must be always considered. Controls are of value because the purity of the irritant used for testing may be in doubt and one

TABLE IX.—PATCH TEST MATERIALS AND CONCENTRATIONS WHICH SHOULD GIVE NO REACTIONS IN NORMAL INDIVIDUALS AFTER 24 HOURS

Rudolph Mayer

Wearing Material

Feathers, fur, animal hair, plants, typewriter ribbon, leather-small pieces 1.5 by 1.5 cm., slightly moistened.

Materials Used in Arts

Urea, ammonium sulphate, potassium nitrate, sodium nitrate, all in 10% solution.

Materials Used in Washing

Persil, washing soda, sidol, sodium hypochlorite, calcium chloride, all in 10% solution.

Acids

Hydrochloric acid 1%, sulphuric acid 0.5%, nitric acid 0.2%, boric acid, pure or moistened, sulphurous acid, 0.2%, chromic acid 5/10 of 1%, formic acid 1%, acetic acid 3%, benzoic acid 1% in alcohol solution, sodium hydrate 5/10 of 1%, Soda, Na_2CO_3 , 10% solution in water, ammonia 1%, borax-saturated solution.

Woods

Pine, oak, hemlock, teak, satin, ebony, powdered and moistened.

Bleaching Powder

Pure and moistened.

Aromatic Oils All in 1% Alcoholic Solution

Citron, peppermint, bergamot, etc.

Alkaloids and Similar Substances

1% watery solution.

Resorcin

1% watery solution.

Soaps

Hard soaps and soft soaps—small moistened piece.
Benzene, 60% in olive oil.
Benzol, 60% in olive oil.
Toluol, 50% in olive oil. Xylol, 50% in olive oil.
Carbon bisulphide, 1/2 of 1% in olive oil.
Trichloroethylene, 50% in olive oil. Mineral oil, 60% in olive oil. Petroleum, 20% in olive oil.
Tar, asphalt, pitch, pure and painted on the skin without adhesive.
Turpentine, 50% in olive oil.
Esters, such as amyl acetate and butyl acetate, pure.
Acetone, pure. Alcohol, pure.

Colors and Color Bases

Shoe and leather colors, 50% in olive oil. Complete oil colors in tubes should be used pure. Other oil colors, 50% in olive oil. Water colors, pure. Mineral colors, pure. Printer's inks and colors, 60% in olive oil.
Anilin, 2% in olive oil or vaseline. Anilin, methylanilin, dimethylanilin and nitrobenzol, 10% in olive oil.
Diazonium salts, 1% in vaseline. (Diazonium salts are used in the preparation of azo-colors.)
Ursol, amidophenol and their homologues, 2% solution in vaseline.

Photographic developers, 5% watery solution.

Reagents

Methylorange, phenolphthalin, 2% alcoholic solution.
Esbach's reagent, Nylander's reagent, sulphosalicylic acid, 10% watery solution.

Disinfectants

Bichloride of mercury and mercury oxycyanate, 1% watery solution.
Formalin, 10% watery solution.
Carbolic acid, 2% solution.
Liquor cresolin 1/2 of 1% solution.
Naphthalin, pure.

Miscellaneous Salts

Sulphur nitrate, 3% watery solution.
Copper sulphate, 10%. Nickel sulphate, 10%. Iron sulphate, 10%. Potassium bichromate, 1/2 of 1% watery solution. Potassium permanganate, 10% watery solution. Calcium nitrate, 10%. Ammonium chloride, 3%. Ammonium nitrate, 10%. Ammonium fluoride, 1/2 of 1%. Sodium fluoride, 1/2 of 1%. Sodium sulphide, 2%. Common salt, 10%. Potassium chloride, 10%.

Fig. 4. Positive patch test with 0.6% solution of dinitrochlorbenzol.

may get false positives with benign concentrations due to impurities. When we are ignorant of the strength of the irritant, controls are necessary. We must always bear in mind the fact that hypersensitivity may be localized. In general, clear areas of the skin near the site of the eruption are the best for testing. Sulzberger and Kerr¹¹ cite a patient whose contact dermatitis was due to face powder and had a positive patch test on the V area of the neck and chest anteriorly while a patch test on the back was negative.

The patch test may again be negative because it does not represent or simulate actual working conditions. Friction may be necessary to produce the dermatitis. Also, there may be sensitivity to an irritant which will not appear by patch test for reasons which cannot be explained. Sometimes heat, or ultra-violet radiation must coexist. It seems that chlorophyll dermatitis is produced with red ray irradiation plus chlorophyll.¹² Photodynamic activity is important in oil of bergamot dermatoses and melanoses due to coal tar and petroleum derivations.¹³ The above being so, we can only submit more strongly than ever to the feeling that the most practical and important test is that of exposing the man to actual working conditions. If every time the man works, he develops dermatitis, and every time he stops, he gets well, his job is certainly a causative factor of his condition. The following are a few cases in point illustrating various types of industrial dermatitis.

CASE 1. Mr. P. B., an Italian, aged 48,

was a cement mixer and brick layer's helper. His dermatitis was on the face, neck, hands, forearms and legs, and had been present for two months. Patch tests, whenever applied with cement and other materials that he worked with, were negative. On inhaling the dust from cement and exposing himself to it, a dermatitis could be produced. A direct rubbing of the cement on the previously affected areas produced a dermatitis.

This case illustrates local sensitivity and secondly shows how friction and a better simulation of occupational conditions were necessary to produce a positive test, and shows the failure of the patch test due to two factors.

CASE 2. Miss B. G., aged 27, was a manicurist employed as such for many years. She presented a dermatitis of the palms and fingers, of four weeks' duration. Patch tests which were done on the back with lemon shampoo, permanent wave lotion, and nail polish remover, exhibited positive reactions at the end of twenty-four hours. The patient discontinued her work, and with emollient applications to the affected areas, the eruption disappeared within three weeks. Upon returning to her usual occupation, there was a prompt recurrence.

This case illustrates the not unusual presence of multiple sensitivity to irritants.

CASE 3. Mrs. B. D., a woman aged 29, a stenographer, presented an eruption on the backs of both hands. Nine months previously she had had a similar eruption which disappeared with treatment. The present outbreak was of one week's duration. Patch tests on the back, with carbon and typewriter ribbon were positive. Treatment with roentgen rays and emollient pastes, together with the discontinuance of her occupation resulted in a clear skin in six weeks.

The repeated attacks with confirmatory diagnosis by means of positive patch tests are of interest in this case.

CASE 4. J. M., a dishwasher in a restaurant, used homemade soaps. He is an example of localized sensitivity proven by positive patch tests on the forearms, hands, and sites near the affected areas (hands and forearms). These tests were negative on the back.

CASE 5. Mr. A. G., aged 27, was employed as a soda fountain clerk, and was exposed to silver polish, scouring powders and soaps. The fingers of both hands (six in all) exhibited paronychia and onychomycosis. A microscopic examination and a culture revealed a *Monilia* infection. Patch tests for his occupational contacts were negative.

Nevertheless, this man's condition should be considered of occupational origin.

We have seen several similar conditions in those exposed to wet and irritating solutions. We believe such conditions predispose strongly to fungus infections. Undoubtedly abrasions and traumatism contribute as predisposing factors. By discontinuing his occupation and with local therapy there was an early regression of his skin condition.

CASE 6. Mr. Z. P., aged 49, was a furrier. This is a case of localized sensitivity to fur and fur dyes. The duration of the skin eruption on both hands was three years. The eruption disappeared while the patient was away from his occupation and promptly reappeared when he returned to it. Patch tests on his back were negative, but were positive locally.

This man's history of recurrence during his occupation is the most positive test of occupational dermatitis.

CASE 7. Mrs. A. M., aged 25, though not an industrial dermatitis case, is nevertheless of interest as a contact dermatitis case secondarily infected with fungus. The patient exhibited the dermatitis in the area where she wore a wrist watch. The test with a leather strap proved to be positive. Her feet exhibited a fungus infection, as did also the area of the dermatitis by culture. Since seeing this case, we have also seen a similar dermatitis in a man who wore a wrist watch which was not complicated by a fungus infection. Up to date there have been thirty or forty similar cases throughout New England.

Tracing the materials used in the manufacture of these watch straps entailed a vast amount of work with as yet an incomplete analysis. The watch maker, the strap manufacturer, the leather jobber, the lacquer company, and the tannery involved, all had to be canvassed and samples of their products involved in the manufacture of the straps had to be collected and used for patch testing. A tour of Lynn, Meriden, New Haven, New York and Philadelphia was necessary for this. The thinner, among the substances involved, seems at the present writing to be incriminated as the offending substance.

Treatment

A person who is sensitive to the material with which he works and cannot develop an immunity or "become hardened" to it should seek some other occupation.

The dermatitis, if uncomplicated, should disappear when a worker is away from the substance which has caused it. It is rarely that cases of chronic, incurable eczema can be positively traced to an industrial irritant. Most cases of industrial dermatitis develop in new employees or employees exposed to a new irritant, and are usually mild in character. Such workers should not be taken off the job. It is much better to give them a protective ointment to put over the parts, protective clothing, and to let them continue working. In general, workers who do not develop an immunity should be taken off the job and placed in some other occupation, if possible. In applying medication to the lesions of an occupational dermatitis, only the mildest form of ointments, lotions, or powders should be used. A mild boric acid ointment or a calamine lotion with perhaps a weak solution of an anti-pruritic, such as phenol, have been found to be efficacious. When the diagnosis is known in selected cases, the use of the Roentgen rays in fractional, non-filtered doses often speeds the convalescence. The coexistence of fungus and pus infections necessitates measures to treat the dual or complicating disease at the same time. Attention similarly must be turned to constitutional factors. The elimination of a focus of infection is sometimes followed by a clearing up of a persistent occupational eczema.

In certain cases desensitization of the patient may be tried. The procedure may be difficult and prolonged, and the results uncertain. However, the literature cites many successful instances.^{10,14,15} The vegetable oil contact dermatoses seem to provide the most promising results. The "Allergenic Oils" (Lederle) may be useful both in treatment and desensitization.

Prevention

The ideal method of prevention is to safe-guard the industries which have skin hazards so that the injurious chemicals will not come in contact with the skin of the worker. This can be and has been accomplished in many factories where the entire process of manufacture is totally enclosed. The raw materials are sucked up into reservoirs from which they flow into retorts and tanks merely by the turning of a valve. The finished product

is barreled without the worker having come in contact with any of the intermediates of the manufacturing process. Modern factories are being built to conform, in so far as possible, with this standard. In some places the worker must be protected against irritating substances by wearing suitable protective clothing such as rubber gloves, aprons, masks, goggles,—and by the application of protective ointments.¹⁶ The actual elimination of unessential, strongly eczematogenous chemicals is being carried out. For example, hexamethylenetetramine in the rubber industry has been largely discontinued as too much of a hazard. The examination of new workers for possible evidence of predisposition (referred to above in this article) would be of some value in industries and processes in which the dermatitis hazard is high. In factories where synthetic dyes and complex organic compounds are manufactured, new applicants should be patch tested with the chemicals with which they will be called upon to work, and those found to be hypersensitive should be rejected. There should be periodic routine examinations of the workers in search of those who have skin and other ailments, and those found should be given prompt attention.

The proper ventilation of workrooms is of prime importance in the prevention of occupational skin hazards. If the irritating gases or dusts are sucked away from the workers, there will be fewer cases of dermatitis. Exhaust hoods should be properly placed over processes giving irritating dusts or gases. Floors should be washed out at the end of each shift to remove dust. Cleanliness should be emphasized. Shower baths and lockers should be provided for the workers, and they should be required to use the showers and change from working to street clothes after each shift. It has been found that furnishing clean work clothes to the workers every day stopped outbreaks of dermatitis. In oil refineries the wearing of clean work clothes and the compulsory use of shower baths has stopped the occurrence of oil acne and oil boils, and has lessened the incidence of tumors of the skin.

In occupations where the worker is exposed to irritating dusts such measures

have also helped in the abatement of dermatitis. Protective ointments have been found useful temporarily, pending the installation of other more suitable preventive measures.

Legislation

Laws for compensation for industrial skin diseases are not uniform in different states. Only eleven states have laws for the compensation of industrial skin diseases. Some of these states specify the causes for which skin diseases are compensated; others do not. It would be very desirable to have model laws for compensation drafted and made uniform throughout all of the states. Most of the states that compensate for skin diseases have lay boards to decide whether a disease is or is not of occupational origin. Doctors are called to testify before these boards, and very often an unfavorable impression is made by so-called experts giving opposite opinions. The boards cannot know that an unjust claimant may have asked many experts to testify in his favor before he found one unscrupulous enough or ignorant enough to do so. They only see two experts, of equal standing as far as they know, giving opposite opinions, and the result is that the board forms wrong impressions as to the honesty and knowledge of the medical profession. Moreover, the board is more likely to be impressed by the positive and glib answers of a loquacious charlatan than by the quiet and scientifically reserved opinions of an ethical specialist. Compensation boards should be composed or be guided by the opinions of an impartial group of State-paid physicians totally divorced from politics if possible, and chosen for their familiarity with industrial processes and industrial diseases.

It certainly is advisable for the physician handling these cases to be familiar with the compensation law of his own state. Even then, legal advice concerning past court decisions on cases appealed to higher courts may be of interest in the matter of how the law has been interpreted in the past in similar cases.

A brief description of some of the industries actually studied follows:

Rubber Industry. Rubber itself is rarely the irritant. Cases of dermatitis caused by wild rubber are possible, that is from ruh-

ber which is obtained from South America and Africa which is smoke cured in contradistinction to plantation rubber, which is acid cured. In smoke curing, the products of combustion, such as acetic acid, phenol and tarry matters, are impregnated in the rubber and may irritate sensitive workers. The accelerators which have caused the most trouble have been hexamethylenetetramine, trimene, tuads and paraphenylen-

Fig 5 Mineral oil folliculitis of the thigh caused by oil saturated clothes

diamene Hexamethylenetetramine and "ppd" are used very little at present in the rubber industry. Properly cured or vulcanized rubber is very rarely the cause of irritation. Among rubber workers it is chiefly the uncured compounded rubber that causes dermatitis. Among the wearers of rubber goods it is usually the excess of accelerator or anti-oxidant which "blooms out" on cooling of the rubber leaving a fine powder of these chemicals that causes a dermatitis.

Oil Industry In this industry the handlers of oils, greases, and waxes may develop conditions varying from a folliculitis to nodular growths. Paraffin pressmen develop wax warts on the arms and hands. Cancer has been found to occur with unusual fre-

quency in this industry. Oil boils or oil acnes are also very common. Oil acne differs from acne vulgaris in the fact that it forms around the hair follicle and not around a sebaceous gland and it occurs on the arms and legs, not on the face and back.

Heavy Chemicals. Dermatitis in this industry occurs very frequently. Acid and alkali burns are common and many of the chemicals have an irritating action because of their acidity. Such cleaning agents as tri-sodium-phosphate and metasilicate of soda act as irritants on the skin of workers handling them. Burns with chloride of zinc, sodium fluoride, and soda ash are common among workers handling these products. Many of these substances cause irritation of the nasal mucosa and even perforation of the septum. Chromic acid and its compounds, the fluorides, the cyanides and some of the compounds of arsenic are examples of such substances.

Synthetic Dye Manufacture. Very few of the finished dyes are general irritants. If they were, people could not wear dyed goods. A few of the dyes, such as paraphenyldiamene, bismarck brown, auro-

Fig 6 Dermatitis caused by dinitrochlorbenzol, an intermediate dye used in the manufacture of sulphur black.

mine, saffranine, crystal-violet, malachite green and anilin black, do cause dermatitis among a small percentage of workers handling them and also among hypersensitive people who wear materials dyed with them. We have found that dermatitis apparently caused by dyed goods was often due not to the dye, but to the finish used on the goods. These finishes consist of sulphonated oils, some of which are not properly neutralized; also of compounds of formic acid. Many of the intermediates used in the manufacture of synthetic dyes are irritants. The sulphonic acids of the various organic compounds which are intermediates in synthetic dye manufacture contain sufficient sulphuric acid to cause dermatitis. Dinitrochlorbenzol is probably the worst irritant in synthetic dye manufacture. Many of the workers are highly sensitive to this product.

Many of these intermediates are also sensitizers, that is, exposure to them for a length of time will cause a previously immune person to become hypersensitive. This is especially true of the nitro and the nitroso compounds. In the manufacture of synthetic dyes, the men who handle the filter presses, the flaking machines, the dryers and the grinders are especially exposed to irritants. The older machinery caused more exposure than the modern installations. The newer types of plants are so constructed that the process is totally enclosed, there being no contact with irritating materials from the raw to the finished product. Containers are emptied by suction into tanks and these tanks communicate with kettles by means of pipes and their contents can be interchanged simply by turning a valve. The kettles are provided with suction ventilation so that when they are opened, fumes are drawn away from the opening. Filtering of materials is done in totally enclosed continuous suction filters which discharge their product into drum dryers which in turn discharge their product into totally enclosed grinders from which the final product is poured into barrels. In such plants the incidence of dermatitis is very small.

Leather Tanning. The most serious health hazard in leather tanning is, of course, anthrax. Fortunately, it is of rare occurrence. The chemicals used in leather tanning are frequently the cause of dermatitis. The chromates cause dermatitis and ulcers. Lime, sodium sulphide, and arsenic are used as unhairers. They also cause dermatitis. Sometimes, sumac is used as a tanning agent, and hypersensitive workers develop a dermatitis from it. The leather

dyes are often blamed for causing dermatitis, but are actually rarely at fault.

Rayon Industry. The two principal forms of rayon manufacture are the viscose method and the cellulose acetate method. In the viscose method, wood pulp is exposed to sodium hydrate, which softens and swells it. This product is then shredded and stored for ageing. It is then submitted to the action of carbon bisulphide in a revolving drum,

Fig. 7. Synthetic dye worker with an acute "oleum" dermatitis or burn.

resulting in a compound called cellulose xanthate. This is dissolved in a solution of sodium hydrate, forming a substance called viscose. The viscose is forced through revolving orifices called spinnerettes into an acid solution which precipitates the cellulose and forms the rayon thread. The thread is spun and spooled and then bleached, combed, dyed and woven into rayon material. The viscose is also forced through narrow slits into the precipitating solution to form sheets of cellulose called cellophane. Dermatitis occurs among the men handling the spinnerettes due to the action of the acid solution into which the viscose is forced. Viscose is highly caustic and burns the skin if not quickly wiped off. In bleaching rayon, chlorine is extensively used and dermatitis sometimes results from the bleaching solution. The coning oil, consisting of sulphonated vegetable oils, also causes dermatitis in susceptible workers.

Bottle seals are also made of rayon and have caused dermatitis among handlers of wet rayon bottle seals.

Acetate rayon is made by an entirely different process. Cotton linters are subjected to the action of glacial acetic acid and acetic

anhydride and sulphuric acid. The resulting jelly-like substance is saponified and then neutralized and the cellulose acetate is precipitated by washing with water. After drying, it is dissolved in acetone and then forced through spinnerette machines and wound into threads. No dermatitis occurs but cases of burns from the acetic acid are very common.

In preparing silk for weaving and knitting, called silk throwing, dermatitis occurs among the girls who handle the wet silk. This is due to the wetting solution which often contains a high percentage of soap. The soap is the actual irritant.

Systemic poisoning by carbon bisulphide and hydrogen sulphide occurs at times among workers in rayon. Carbon bisulphide may be breathed when cellulose xanthate is made and hydrogen sulphide is liberated over the precipitating tanks. In making cellulose acetate, acetone jags occur at times in the hot filter rooms.

Linseed Oil. We have investigated outbreaks of dermatitis among workers of linseed oil. Dermatitis in this industry can be caused by the sharp seed points in the linseed oils; by parasites; by oils of mustard and rape which contaminate the linseed, and

by the filter mats used, which are made of human Chinese hair.

Miscellaneous. In candy making, the sugar and the essential oils used for flavoring are causes of dermatitis. In the manufacture of formaldehyde, hexamethylenetetramine, the dermatitis usually occurs among men working in the dryers. In explosive manufacture nearly all the materials used are irritants. Ground glass, oxidizing agents, like potassium chlorate, manganese dioxide; explosives like fulminate of mercury, T. N. T., lead azide, lead styphnate, tetryl, dinitrofluene, are examples. Workers with lead styphnate have their hair and skin turn yellow, very much as if it was dyed with picric acid. Workers with a new explosive called sensol, the formula of which is a secret, often develop dermatitis. Most of these substances, however, are not irritating to everyone, but only to certain individuals.

Dermatitis occurs among the makers of insecticides. The insecticides used for spraying trees and vegetables are usually lead arsenates. Last summer these substances were used in an effort to destroy a plague of grasshoppers in the northern part of the United States and resulted in an outbreak of dermatitis.

A handy compendium of information on the "Control of Communicable Diseases" appears in the August 9 issue of *Public Health Reports* (Washington, D. C.). It is prepared by a Committee of the American Public Health Association and covers every-

thing from actinomycosis and ascariasis to yaws and yellow fever. It treats recognition of the disease, etiological agent, source of infection, mode of transmission, incubation period, communicability, susceptibility and immunity, prevalence, and control.

HAY FEVER AND HYPERESTHETIC RHINITIS

Treatment by Ionization

Lt. M. HURD, M.D., *New York City*

Electroionic medication or medical ionization, properly called iontophoresis, was much in vogue thirty years ago. Then its use subsided until Warwick reported his successful results. Such ionization is the introduction of ions into the skin or mucous membrane by the galvanic current.

The galvanic current can be produced by several methods, namely: (1) Batteries which give a pure constant current. This set up has been made for years by different manufacturers. An inexpensive set has just recently been described by Douglas Macfarlan.¹ (2) The galvanic wall plate where the power line is D.C. current. (3) The motor generator.

A report on tests of three varieties of apparatus by the Westinghouse laboratory is as follows:

1 Wappler Wall Plate. This device operates from the D.C. supply and the output therefore, takes on the character of the D.C. from the power mains. Inasmuch as the ripple in the majority of power systems is entirely negligible, the galvanic output of this machine is similar to the output from a battery in regards ripple.

2 Burdick Galvanic Generator. This device consists of a motor generator set, hence the output will have the characteristics of the generator rather than of the current from the power lines. Measurements made on an oscillograph show that the output at milliamperages up to about thirty was almost entirely without ripple, the ripple being so small that it could not be measured with our laboratory equipment.

3 Another Make of Galvanic Generator. This machine also contains a motor generator set with the result that the current delivered has the characteristics of the generator. The generator output has a considerable amount of ripple, the percentage varying with the milliamperage output of the machine. With small amounts of output the percentage ripple is quite small and the percentage increases when the D.C. milliamperage output increases. Oscillograms made at an output of 30 ma. show a ripple content of approximately 8 per cent. The

frequency of this ripple is 1080 cycles per second.

Each type of apparatus has its adherents. It probably makes no difference, as clinically the patients have about the same degree of discomfort, the appearance of the membrane is the same, and so are the after results.

The current is unidirectional, of low voltage and amperage. The positive pole repels hydrogen, alkalis and metals, and a convenient way to remember this is with the initials "H A M P", the "P" indicating "positive". The negative pole repels acid, acid radicals and halogens. The galvanic current produces two effects: (1) physiochemical and (2) physiological. The effects manifest themselves at the point of entry and exit and also along the path of the current between the poles.

The effect at the poles is simple, but what takes place along the path of the current through the body is still undetermined and subject to much controversy. If the two terminals are metallic plates and are placed against the wet skin, there will be caustic effects. The sodium chloride of the body fluid will break up into caustic sodium hydroxide at the negative pole and hydrochloric acid at the positive pole. To overcome this destructive action both poles, metallic terminals, must not come in direct contact with the skin or mucous membrane but must be separated by a pad of cotton or the electrolyte. The pads must be sufficiently thick so that the caustic chemicals from the metallic poles cannot diffuse to reach the skin and mucosa.

As the current flows through the human body many complex factors come into play besides the action on the sodium chloride. In the body, there are also colloids and other metals and acids. There must be migration, or at least redistribution of ions in the body between the poles, but if the current is kept within

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 15, 1935.

physiological limits, there are no demonstrable physiological effects.

Electroionic Medication

Iontophoresis or ionization is the attempt to pass certain drugs or chemicals through the skin or mucosa, by means of the direct current. If an aqueous solution is made of a chemical, there are positive and negative ions liberated which are moving about in a disorganized way. If a constant current is allowed to flow through this solution, the positive ions go to the negative pole, and the negative ions to the positive pole. For example; in a solution of sodium chloride, the sodium ions go to the negative pole and the chlorine ions to the positive pole. Leduc,² thirty years ago, claimed that ionic medication, would place the drug where wanted, in any amount, and demonstrated that strychnine sulphate and potassium cyanide could be passed through a rabbit's skin to kill the animal. Pack³ verified these experiments, but showed salts of heavy metals do not penetrate in the same fashion.

Subsequent investigators demonstrated that different ions moved at a fixed rate of speed which increased with the voltage and diminished with the distance in the electrolyte through which they travelled. The speed is roughly in proportion to the atomic weight. Hydrogen is the fastest, while the heavier atoms are slower. Therefore, the heavy metals like zinc, copper, tin and cadmium are many times slower than hydrogen. The hydrogen ions being present in great numbers in the body fluids, carry nearly all, if not all of the current, while the ions of the heavy metals being very much less numerous, probably do not transmit the current at all.

It has also been demonstrated that the moment the ion of a heavy metal comes in contact with the body, it loses its charge and combines with the proteins; and the effect taking place beyond the mucosa is due to the passage of the current only. Pack et al.,³ found that mercury was not absorbed and came to the same conclusion as Turrell.⁴

The zinc ion attracted from the positive electrode to the negative pole, on arriving at the surface of the body, lags behind, and the current is carried on much faster by the

hydrogen ions of the tissues. The zinc ion is thus set free to enter into chemical combination with the tissue constituents and forms an oxychloride of zinc, which is electrically deposited upon the superficial tissues. The process is one of electrodeposition resembling the electroplating of commerce. The skin or mucous membrane thus forms a virtual negative pole.

This assumes that there is a superficial deposit of zinc combined with the proteins to form the zinc albuminate. Friel⁵ says ionization is strictly a local treatment and, therefore, should be applied to the whole area. Lierle and Sage⁶ state in conclusion: "The possibility of the deposition of metallic zinc in living tissues is remote and open to question."

McMahon⁷ shows that; "ionizing with zinc sulphate, the dog's normal frontal sinus mucosa causes marked changes in the mucosa. Namely engorgement of all the capillaries of the subepithelial tissue. There was also present a marked extravasation of red blood cells into the edematous subepithelial tissues, and certain more or less extensive destructive changes in the epithelium."

My own examination of polyp tissue before and after ionization, showed, with the same dose as McMahon used, some increase in edema to a definite coagulative effect which had fairly well penetrated through the polyp, but no necrosis. It is possible that the difference between McMahon's findings and mine is the difference between normal mucosa and polypoid tissue.

When zinc sulphate is dissolved in water a proportion of the molecules split up into two fragments, namely: (1) an atom of zinc, (2) a group of atoms of SO_4 . A solution of a substance in water which undergoes this dissociation into fractions is called an electrolyte. The positive and negative fractions of the electrolyte are called ions. Positive ions are called kathions, negative ions are called anions. It has been found that the dissociated molecules in a concentrated solution increase the resistance to the motion of the ions among them, therefore, if one increases the dilution until a point is reached where dissociation is complete, the maximal value of electrolyte conduction is reached. Therefore, the weaker the solution the better and the

strength of zinc sulphate should be $\frac{1}{2}$ per cent.

Ionization of the nose has a few advocates, Friel,⁸ Crabbe,⁹ and Franklin,¹⁰ in England and Hollender,¹¹ and Warwick,¹² in the United States. The latter claims much better results by adding a small quantity of tin and cadmium to the zinc, and on account of his claim Alden,¹³ took up his technic and has reported such favorable results that it has created a furor for this method of treating hay fever and hyperesthetic rhinitis (allergic coryza).

Warwick lays much stress on technical detail, namely that the electrode must be used only once, the resistance must be low, the electrolyte must be the one which the Burdick Company puts out in ampoules, and his special generator the only one which will give the proper current.

There was some criticism that these formulae were kept secret, but finally a mimeographed formula from the Burdick Company stated that the electrode was composed of zinc 97.1 per cent; tin 1.9 per cent; and cadmium 1.0 per cent. An electrode which I had analysed was found to contain zinc 91.8 per cent; lead 3.83 per cent; tin 2.54 per cent; and cadmium 1.70 per cent, also a trace of bismuth and iron. This led me to believe that it was made from an impure zinc metal. The present electrode contains the proportion of zinc, tin and cadmium as stated: zinc 86.04 per cent; tin 9.48 per cent and cadmium 4.34 per cent.

At first the electrolyte was said to contain zinc sulphate grains 9; stannous sulphate 0.9 grains, cadmium sulphate 0.45 grains, and a blue dye. My examination of the contents of the ampoule showed undissolved violet dye and the presence of zinc and cadmium sulphate, and no tin. The present formula has been changed to zinc sulphate 8.92 grains, stannic chloride 1.42 grains, cadmium chloride 0.45 grains, to the ounce. This would lead one to believe that the formula need not be so exact, and is subject to modification and improvement. It is better to have the electrode of the same metals as the salts in the electrolyte, as the acid radical will attack the electrode and form more ions of the same sort.

Remembering that the ions travel with

a speed in relation to their atomic weight (zinc 30, cadmium 48, tin 50), theoretically it would seem that the zinc ions would be deposited much faster than the other two, and considering the much larger proportion of zinc, that the amount of tin and cadmium deposited in the tissues would be very little indeed. How much this is an improvement over straight zinc ionization remains to be determined.

Warwick claims that the resistance of the circuit must be kept low; if it is high the nose must be repacked as it was not done properly at first. This is true as the lower the ohmage or resistance, the lower the voltage will be, and this will mean less discomfort for the patient; but, it is not always possible.

The first reading of the ohmage, as soon as the connections are made, may be high, and after passing a constant current of a couple of milliamperes for a few seconds, the ohm reading will be several thousand lower. It depends as much on the hair, skin and fat of the arm, which have high resistance, as on the condition of the electrolyte in the nose.

Technic

Granting that you have an apparatus to generate galvanic current, whether it is an inexpensive battery set-up or a Burdick machine, it should have meters so that you may know how many ohms, volts and milliamperes you are using.

The Burdick apparatus is especially built for nasal ionization, and eliminates error, as far as possible in a machine. This has ohm and milliamperage meters, terminals which plug in, so that you cannot make a mistake as to poles, a clock which times length of current flow and also turns off the current slowly at end of treatment, so that there will be no shock.

According to Warwick, the nose should be anesthetized, then carefully packed with cotton strips saturated with the electrolyte, and the metal electrode which has been wrapped with cotton, introduced in the center, and more cotton packed around it. The arm cuff separated from the skin by a pad saturated with saline is placed on the forearm, after the skin has been cleaned with a grease solvent. The negative pole is connected to the arm cuff, and the positive to the electrode in

the nose. The ohm meter reading, if satisfactory, should be between 2000 and 3000. According to Ohm's law, amperage equals voltage divided by ohmage. Two factors being known, it is easy to obtain the third. For example, ohms being 3000, milliamperes 10, multiplying ohms by milliamperes gives 30 volts. If 6000 ohms, it would be 60 volts, so it is well to have the resistance as low as it can be obtained by good contacts at the two poles. Warwick advises a dose of 100 milliamperes minutes, that is, 10 milliamperes for ten minutes.

This dose is arbitrary as it depends on the surface area of the nose, as well as the time and current. For example, if one nose had an area of forty square centimeters, and received 100 milliamperes minutes, another nose of eighty square centimeters would have to have 200 milliamperes minutes to receive the same electroionic dose.

The current is gradually turned on until it reaches the milliamperage desired. As soon as the current begins to flow at the required strength, the patient notes a metallic taste, and there is an increased flow of secretion from the eyes, nose, and mouth.

After the current has flowed for the required length of time it is gradually turned off and the nasal packs removed. The nasal membrane is found to be contracted and coated with a grayish white deposit.

The patient now complains of a headache which will become severe and last for several hours, requiring a sedative. The nose becomes obstructed and the next day the mucosa is covered with a jelly-like fibrin, which persists for from three to five days, during which time there is almost complete nasal obstruction. The fibrin should be allowed to come off spontaneously. The membrane will remain red for some days following.

I have made some modifications in the technic, abandoning the clumsy Burdick cuff, because it was hard to get good contact, and the patients complained of disagreeable sensations in the arm, and using the old method of the flexible sheet metal, very heavily padded with cotton (one-half inch thick when wet), saturated with normal saline, as the large negative electrode. I administer atropine sulphate, gr.

1/150 before the treatment, in order to reduce the unpleasant salivation, and now use the method of flooding the nose with the electrolyte instead of packing, which was very uncomfortable, and in many cases, on account of anatomic irregularities it was impossible to pack satisfactorily.

Mr. Anderson, president of the Burdick Company, gave me a "U" shaped glass tube for this purpose, which I found was devised by J. Sandison Crabbe of Birmingham, England, in 1920. Gale,¹⁴ devised a similar tube which was also used in the same way. I have used a simpler and less awkward tube which is made with a hard rubber nasal tip, connected with rubber tubing to a small glass tube just large enough to admit the electrode. Near the end of the glass tube a piece of tape is tied. At the other end of the tape is a two ounce lead weight. The rubber tubing is three inches and the glass tubing four and one-half inches long. The patient bends forward until the face is parallel with the floor, the nasal tip is held tightly in the naris by the patient, and the glass tube is brought up vertically beside the patient's ear and held there by the tape which is passed across the back of the head and held in place by the weight. By this method the nose is flooded until the electrolyte runs out of the opposite naris, and the electrode is inserted into the electrolyte in the glass tube. There is much less discomfort, in fact, it is a pleasure to the patient compared to packing, and is superior to packing as all mucosal surfaces are in contact with the electrolyte, which is impossible by the pack method. All good things have a drawback, and in this case, it is that the olfactory cleft is included, whereas in packing it is not, and the result is an anosmia which remains for some weeks.

Results

Warwick¹² reports forty cases treated over a period of more than a year previously, with practically 100 per cent results, principally for hay fever, a few cases of hyperesthetic rhinitis, and three cases of asthma with hay fever. Many of these have had no recurrence for from one to six years, a wonderful record.

Alden¹³ treated nineteen cases in 1933 for autumnal fever during the attack, and

all were relieved. Nine had no recurrence the second year, two had similar symptoms as in 1933, eight had such mild symptoms that he did not think it necessary to re-ionize them. In 1934, forty-one cases were ionized prior to symptoms, 50 per cent were free of symptoms.

The Burdick Company has compiled the results of many men who used the method of Warwick during 1934, and a few cases in 1933. Roughly the cases are:

<i>Hay Fever</i>	<i>Cases Reported</i>	<i>521</i>
95-100% improved.....	302	58.0%
85-90% improved.....	44	8.4%
75-80% improved.....	43	8.2%
60-70% improved.....	20	3.8%
40-50% improved.....	46	8.6%
less than 30% improved.....	8	1.5%
no relief.....	58	11.1%

<i>Asthma</i>	<i>Cases Reported</i>	<i>194</i>
95-100% improved.....	76	39.0%
80-90% improved.....	8	4.1%
70-80% improved.....	17	8.7%
60-70% improved.....	9	4.6%
50-60% improved.....	25	12.8%
40 and under improved.....	5	2.5%
no relief.....	54	27.7%

<i>Hyperesthetic Rhinitis</i>	<i>Cases Reported</i>	<i>111</i>
95-100% improved.....	47	42.3%
80-90% improved.....	8	7.2%
70-80% improved.....	15	13.5%
60-70% improved.....	3	2.7%
50-60% improved.....	10	9.0%
less than 40 improved.....	8	7.2%
no relief.....	20	18.0%

<i>Allergic Conjunctivitis</i>	<i>Cases Reported</i>	<i>6</i>
Completely relieved.....	4	no relief 2

<i>Urticaria</i>	<i>Cases Reported</i>	<i>22</i>
Completely relieved.....	3	no relief 17
Moderately relieved.....	2	

<i>Migraine</i>	<i>Cases Reported</i>	<i>2</i>
One moderately relieved...one slightly relieved		

Allergic Dermatitis not urticaria?
Two cases not relieved.

Hollender,¹¹ using zinc sulphate, reports very much the same results for hyperesthetic rhinitis. Franklin¹⁰ reports hay fever 50 per cent, hyperesthetic rhinitis 60 per cent free of symptoms. He uses zinc sulphate 1 per cent and gives three treatments using three to five milliamperes for from 12 to 20 minutes.

Case Reports

A woman, age 27, for ten years has had a watery nose which had become so bad that she could not work on account of constant nasal drip, and sneezing, who was thoroughly tested by two expert Allergists with no results, showed a very pale and swollen mucosa with a profuse serous dis-

charge. She was ionized over a year ago, all symptoms are now relieved although the mucosa is still pale. She has since discovered three things which caused her symptoms, pineapple, peas, and something which is in a package called "Spaghetti Dinner."

A man age 26, for six years had hay fever and autumnal fever, and for the balance of the year sneezing and nasal discharge up to 9:30 A. M. daily. He received protein injections with no result. He was ionized last June and immediately afterward went on a four thousand mile automobile trip through the middle west. He has had no allergic symptoms since, and fewer colds. He presented himself one year later with tree pollen coryza.

Another illustration where the mucosa was only wet with electrolyte is of a girl twenty years of age. Nasal obstruction for two years, watery discharge, sneezing, burning sensation in nose and eyes. Many eosinophiles in the discharge, 10 per cent in the blood smears. She was ionized by the flooding method instead of packing. The technic was poor, most of the electrolyte leaked out and there was none in the nose when the tube was removed. Warwick solution was used on one side, zinc sulphate 2 per cent on the other. After reaction was the same on both sides. She was relieved except that she sneezed about once in three days. In this case the mucosa was only wet, not covered with the electrolyte, yet a very good result was obtained.

I am not ready to tabulate my results, as in some cases I have used the Warwick method, in others the Warwick on one side and another technic on the other side, and in still others a different method.

In cases of hay fever ionized during the attack the percentage of good results has been very high, in hyperesthetic rhinitis over 70 per cent of the cases have become symptom free.

Conclusions

1. The nasal mucosa shows microscopic changes immediately after ionization.
2. Zinc ions do not enter the tissues in any appreciable amount.
3. There is marked clinical reaction of the nasal mucosa lasting about one week.
4. Symptoms of hay fever disappear immediately after ionization in nearly all cases.
5. Hyperesthetic rhinitis is relieved of symptoms in the majority of cases.

Discussion

DR. CLAUDE G. CRANE, *Brooklyn*—I wish to express my appreciation for the opportunity to discuss Dr. Hurd's paper. Dr. Hurd has acquired the art of brevity, and I shall endeavor to follow his example. Dr. Hurd has described the technical details of ionization, in general, so well, that any comments from me would only consume time, without adding anything whatever.

It is evident however, that a distinct change takes place in the mucosa and submucosa, following ionization. As Dr. Hurd stated, McMahon has demonstrated that the mucosa of the frontal sinus, following ionization, undergoes not only a sub-mucous hyperplasia, but a destructive process as well. Warwick had examined the mucosa and sub-mucosa, before and after ionization, and found no destructive process had followed ionization, and that the change in the submucosa was apparently permanent.

I agree with Dr. Hurd, that the dose must of necessity vary, with the area of the mucosa in the individual nose. The use of atropine before treatment is certainly a help in reducing the profuse secretion from the nose and the salivary glands.

Dr. Hurd's method of flooding the nasal cavity with the electrolyte solution should avoid the unpleasant features of the packing method, and should place the solution in contact with every part of the mucosa. The anosmia which results, while unpleasant, is not serious if one can be sure of no permanent damage. Dr. Hurd, I am sure has satisfied himself that the result is only transitory. In the event of the need for several ionizations, we should consider the possible results of repeated ionization on the olfactory area.

My experience with ionization began in February, 1934 and I have confined my treatment to hayfever, asthma, and hyper-esthetic rhinitis.

We may consider two main groups—the extrinsic and the intrinsic. In the extrinsic group, we have all of the inhalation and ingestion cases. In the intrinsic group, we have all of the bacterial and endocrine cases. In the treatment of all of the groups it is evident that the elimination of the specific cause is not only the simplest, but the most efficient method of choice. Whenever this is possible, we have no occasion to search further for satisfactory treatment. This elimination is very simple when the cause is confined to a single factor. Whenever it is not possible to eliminate the cause, we have to resort to some form of desensitization.

Immunization by hypodermic treatment, with extracts of the offending foreign protein, whether pollen, dust, or other proteins, I need only mention. The ingestion group may also be satisfactorily taken care of by the elimination of the particular food, or foods, whenever one or two foods are involved. This may offer the most satisfactory treatment, however, this may not be practicable and immunization by use of extracts is indicated. At this point I wish to mention that I believe the elimination diet offers the most reliable diagnosis.

In the intrinsic group I will only acknowledge the endocrine cases, the bacterial cases presenting the satisfactory group for treatment. We culture every possible area separately and note the skin reaction from each group. Whether one uses the scratch method or the intradermal method, bear in mind that the reaction, if positive, requires a longer period to manifest itself than the pollen or food reaction.

In considering positive or negative skin reactions, it seems to me we should bear in mind that the skin and mucosa of any individual need not be equally sensitive. This accounts for some of the negative, or moderate skin reactions.

In the bacterial cases, a thorough clean-up of all areas of infection should be attempted. This may require surgical attention, or conservative measures may be indicated. With this accomplished, in whole or in part, as may be possible, the patient should be immunized by use of vaccines made from the bacteria found on test to be positive. The same principles apply for immunization treatment, whether one is using pollens, dust, foods, bacteria, or any other protein. All of the foregoing is so familiar to all of you that there is no occasion to elaborate further.

We will discuss a rather large group, which includes all of the groups, classified according to etiology. To this group, belongs all those cases, in which, either elimination of the cause, or immunization has been found totally inadequate, or sufficiently so, to afford the patient satisfactory relief from symptoms. It is in this group that so many methods of therapy have been used with varying success.

For the most part, we can term this type of therapy as 100 per cent empirical. I will merely mention a few of them. Caution of the nasal mucosa, with heat, or chemicals, to the point of tissue destruction; desensitization, by injection of alcohol, into the inferior turbinate, or septum, or, into the anterior nasal nerve; injection of alcohol to desensitize the sphenopalatin ganglion by the Sluder technic, or through the posterior palatine canal (Ruskin). In literature from time to time, we have had reports on a series of cases treated very successfully by these various methods.

Concomitant with these enthusiastic and optimistic reports, we have had reported a series of cases, in which the same therapy has been used with total failure. Between these extremes, we have had a varying attitude toward all of them.

It is evident that we have had presented to us, many cases which have been so discouraging that any new method offered, attracts our attention and tempts us to try it. This is especially true if we are convinced that the measure is without any deleterious results, and the technic of application is practical and without much discomfort to the patient. Ionization meets these requirements.

Ionization for hyperesthetic rhinitis was used by Demetriades in Vienna over ten years ago. His method was crude, but he obtained some relief of symptoms. Franklin of London improved the technic and in 1931 reported some permanent cures.

About eight years ago, Warwick began his experimental work with ionization in the treatment of hay fever, asthma, hyper-

esthetic rhinitis, and allergic rhinitis, due to food allergy. In his first attempts he used zinc alone in the electrode and in the electrolyte. He found this resulted in severe reactions, and sometimes in the destruction of the mucosa. After experimenting with various combinations of metals, he selected a combination of zinc, tin, and cadmium, both for the electrode, and the electrolyte solution.

This resulted in less local reaction and gave the best therapeutic results. He perfected a galvanic machine which delivers a direct current, and is so constructed as to make an accurate measurement of the proper resistance, and current delivered.

It is essential to successful treatment that the technic be strictly adhered to in every particular. It is also important that any definite pathology within the nose be taken care of before treatment is started. If obstruction is present, sufficient to make it difficult or impossible to properly pack the nose and insert the electrode, such obstruction should be corrected before beginning treatment.

The theory on which the treatment is based, is for the most part empirical; however, it has been demonstrated that the sub-mucosa undergoes a definite hyperplasia, and on this a new membrane is formed which is not sensitive to proteins whether they be inhaled or ingested.

The sphenopalatine ganglion desensitization theory has its advocates but is doubted by some as alcohol injections are not successful.

It is probable that the ionization desensitizes the ganglion more effectively than does the alcohol. It was believed at first that the desensitization was purely local but it is more than likely that there is a more remote reaction, as indicated by the favorable results in urticaria, without nasal symptoms. I will not attempt to present to you, in detail, the many reports from all over the country, on the highly gratifying results of ionization. A list of the men of outstanding ability and reputation who have reported favorably, is, in itself, most convincing.

I might mention that the electrode consists of sulphate of zinc, 85 per cent, tin 10 per cent, cadmium 5 per cent. The solution is in the same proportions.

Tobey has reported sixteen cases with a conservative estimate of 85.6 per cent relief; of these cases, eight had hay fever, and gave 85.6 per cent relief. One was treated two months before the expected fall attack with no symptoms for the first half, but the last half showed the usual symptoms. All of his patients treated

after the onset of symptoms were 100 per cent relieved of all symptoms. One of his patients had urticaria asthma and hyperesthetic rhinitis, and was relieved for six months.

Alden in St. Louis, and the Jackson Clinic in Madison, found that the seasonal cases treated in 1933 were, with very few exceptions, free of symptoms during the 1934 season. Many favorable reports could be cited, but there is no occasion to present them to you, as you are as familiar with them as I. The consensus of opinion seems to be that the best results in seasonal cases is obtained when the ionization is given after the symptoms have begun. There seems to be a condition of the mucosa at that time which offers a more favorable soil for the ionization.

The use of the electrode for more than one treatment is not advocated by Warwick. He states that chemical analysis of the electrode, both before and after treatment, reveals a change in the chemical make up of the electrode, making it unsuitable for more than one treatment. I have tried using it once only, and have also used it twice, but I have not been able so far to draw any conclusions. Some time ago I decided to use the electrode more than once. The seasonal cases I treated last year gave the most satisfactory results when treatment was begun after the symptoms had developed.

The perennial hyperesthetic rhinitis

cases I have treated have given me excellent results. The chronic asthma cases present the greatest difficulty and certainly are discouraging. I have had some cases which were relieved only 10 per cent. I have, however, had some cases which have had 100 per cent relief, although this represents a very small percentage. Between these two groups, I have been able to relieve them sufficiently to justify the attempt; all of these cases presented a total failure from every other therapeutic measure.

Last April I spent some time with Warwick, and was much impressed with the amount of research he had done to perfect his present technic. In treating these allergic cases, we should not lose sight of the various factors that enter into the problem. I believe that, even though we use ionization, every phase of allergy should be given proper attention. We should keep in mind that, no matter how excellent the result obtained from any local treatment, we have something more basic at fault in many instances. These cases are over on the alkaline side; and we should institute treatment to restore the acid-alkaline ratio.

I am sure that ionization has a definite place in our therapy, for those cases which have not responded to other measures. I am also convinced that it may very well be a satisfactory substitute in many cases, which may respond fairly well to immunization, but are difficult to control.

MISSISSIPPI'S STRONG MEDICINE

Driven to drastic measures by the alarming increase in unjustified malpractice suits, the Central Medical Society of Mississippi has adopted a series of resolutions stating that to carry these suits through the courts often requires the collusion of members of the legal and medical profession; and speaks of them as legalized blackmail. In order to combat this increasing tendency the organization has forbidden every member of the Society to give evidence in malpractice action unless the testimony has been examined and proved by those designated in the Society for the purpose. Through various steps all the evidence is investigated and then put up to impartial medical "consultants" who then will express in writing their individual opinion as to the validity of the suit. The physician will then be encouraged, or forbidden, to testify according to the opinion of these who are considered to be absolutely fair and impartial experts. If, after the decision has been arrived at, the physician goes ahead and

testifies without paying proper attention to this decision he will be expelled from the Society for unprofessional conduct.

Physicians in Germany are not permitted to have a joint practice or medical partnership.

Many chronic typhoid carriers in this State have been cured of this condition by removal of the gall bladder, according to a report of the State Department of Health. The mortality was high in the cases over 50 years of age. "It is, therefore, advised that when contemplating a gall bladder operation on a typhoid carrier, due consideration be given to the age and health of the patient, that preliminary duodenal specimens be examined in each case to make certain that the focus of infection is in the gall bladder."

FACTS CONCERNING THE TREATMENT OF ANEMIA

WILLIAM P. MURPHY, M.D., Boston, Mass.

Slightly more than one hundred years ago Dr. Blaud described a method of treating an anemia which occurred most frequently in young women which was known as "chlorosis" because of the peculiar greenish tint which was observed in association with the pallor occurring in these patients. Excellent results in the treatment of this condition were described with the use of ferrous carbonate ("Blaud's pills"), usually given in gradually increasing dosage until large amounts of iron had been administered. Although the results of treatment by this means, reported even as late as 1903 by Christian, were satisfactory, the need for large doses of iron and the value of the graded scale administration were lost sight of for a number of years. There then ensued a period of small dosage accompanied by a lack of interest in the simple or iron deficiency anemias. Interest has been again aroused during the past ten year period of more intensive study of the blood dyscrasias, probably largely stimulated by the introduction of the liver treatment for pernicious anemia.

During this ten year period we have groped our way uncertainly through a maze of impressions and incomplete studies back to the precepts of Dr. Blaud; that is, moderately large doses of iron preferably administered in a graded scale of dosage.

Before discussing treatment in greater detail, let us first consider briefly the nature of the condition which we are to treat. This part of my discussion is concerned with the consideration of the so-called secondary or hypochromic anemias. In persons afflicted by this condition, there is primarily a deficiency of the hemoglobin rather than of red blood cells. The cause for this may be variously attributed to an inadequate supply or inefficient use of iron, or to loss of blood too rapid for replacement to occur.

Perhaps the most commonly observed cause for such an anemia is loss of blood.

This loss may be acute with sudden depletion of both hemoglobin and color in an otherwise normal individual. As to be expected, the blood levels will return to normal rapidly with the cessation of hemorrhage. But of greater importance from the standpoint of treatment are those individuals who are anemic because of chronic hemorrhage. In such patients the natural supply of iron is depleted through constant stimulation of the marrow there may be exhaustion, particularly associated with certain deficiencies in that formation of hemoglobin is retarded even though the source of the hemorrhage has been eliminated.

A second important group of individuals comprises those who have hypochromic anemia of uncertain origin. This group is almost entirely composed of women varying in age from young to mature old age, but most commonly described between the ages of 30 and 40. This variety of hypochromic anemia has been variously called chronic chlorotic hypochromic anemia, idiopathic hypochromic anemia, and others though often associated with achlorhydria or hypochlorhydria, this is not necessarily present in all cases, and the anemia does not differ in any essential respect from that present in chlorosis. The fact that idiopathic hypochromic anemia is most commonly in women above the age of 30, whereas chlorosis is generally described below that age, cannot be considered as evidence of a fundamental difference between the two conditions rather suggests that anemia is normally milder in the younger age group. No doubt nutritional inadequacies, multiple pregnancies, fatigue, infection, even chronic loss of blood may each have a part in the development of this anemia in the older age group.

It is not my intention to describe in detail the signs and symptoms occurring in this interesting and important group of patients; but I want, particularly, to call attention to the tan-colored blood which is so characteristic of idiopathic

hypochromic anemia in its more severe stages; to the dryness of skin and finger nails; and, to the fact that there may be complaint of soreness of the tongue, but never in my experience associated with the characteristic glossitis which may be present in pernicious anemia.

These cases may readily be distinguished from cases of pernicious anemia by an examination of the stained smear and by a determination of the individual cell volume, which figure may be as far below the normal individual cell volume as it may be above the normal in pernicious anemia. Again, one may be aided by the low icteric index value as opposed to the high reading in pernicious anemia. Finally, this group of cases may have relatively little decrease in the number of red blood cells as compared with that observed in hypochromic anemia resulting from loss of blood, although some of the most striking decreases in the hemoglobin levels are to be observed in this group, the hemoglobin at times dropping to between 2 and 3 grams per 100 cubic centimeters of blood. This explains the often intense weakness complained of even in the presence of higher red blood cell counts than occur in patients with pernicious anemia who may not complain of such extreme weakness.

Of essentially similar nature to idiopathic hypochromic anemia is the hypochromic anemia of pregnancy, which in its more severe form is probably only an aggravation of a pre-existing idiopathic type.

Then there are anemias which occur coincidentally with acute or chronic infection and which are, at least in part, dependent upon the infection.

Inasmuch as each of the groups described lack hemoglobin, the formation of which is dependent upon an adequate supply or utilization of iron, we must assume that treatment with adequate amounts of iron is necessary. It may, however, be important in individual instances to remove any existing focus of infection, to eliminate any source of hemorrhage either before or during the course of treatment or to stress the importance of an adequate, well-balanced diet which will supply the usual needs of the normal body or the unusual need of the individual case being treated.

We have all heard much about the necessity for the addition of copper to the medication of our anemic patients, and how this much needed copper may be supplied by an adequate ingestion of oysters. I am an enthusiastic advocate of the use of oysters, particularly served on the half shell, as a part of my own dietary regimen; but I am hardly convinced that there is evidence to support their use as a medicine for the anemic patient. There is little evidence available to support the idea that it is important to add copper to the iron in the treatment of anemia of the adult.

That whole liver may enhance the formation of hemoglobin seems to be quite definitely proved through the original work of Whipple and his collaborators working with dogs and supported by early work on the anemia of humans in my laboratory at the Peter Bent Brigham Hospital and subsequently by others. We have observed little benefit in these anemias from the various liver extracts when administered by mouth. We have, however, been definitely impressed with the results of treatment, particularly of the idiopathic hypochromic group, by means of intramuscular injections of a concentrated liver extract, such as is used in pernicious anemia, together with iron by mouth. Not only is clinical evidence of improvement more rapid and striking than with the use of iron alone, but also the actual rate of hemoglobin formation has been definitely increased. At the onset usually 1 or 2 vials (3 to 6 c.c.) of the solution (Lederle) is injected followed by 1 vial (3 c.c.) every 5 to 7 days until the desired result is obtained.

Much has been written recently concerning the use of iron in various forms so that I need not go into a detailed discussion of this subject. It seems quite well established that iron is most effective when given perorally rather than parenterally. We still lack evidence sufficient to establish beyond question, the distinct advantage in hemoglobin building of one iron salt over that of all others. The experience in my laboratory is that ferrous carbonate administered as Blaud's pill and ferric ammonium citrate given either in solution or in capsules, are equally efficient, if given in dosages such that the actual intake of metallic iron is compar-

ble. Ferric ammonium citrate is less likely to produce marked constipation and may, at times, prove to be somewhat laxative in its effect. In either case, less disturbance is likely to be precipitated if the increasing dose method of Dr. Bland is used. Ferric citrate proved to be slightly less efficient.

Just what the optimal dosage is for each patient must depend upon the results obtained. Doses of 30 grains (2 gm.) of Bland's pill and 15 grains (1 gm.) of ferric ammonium citrate have, in our experience, given satisfactory results in many instances and larger doses up to 60 grains (4 gm.) of the former and 45 grains (3 gm.) of the latter have been adequate in practically all instances. Although much larger doses are frequently advised, we were unable to note any definite difference in the effect of 45 grain (3 gm.) and 90 grain (6 gm.) doses of ferric ammonium citrate. It is obvious then that in order to determine the relative efficiency of two iron salts, they must be compared in various dosages. It is entirely futile to attempt to draw conclusions from a comparison of only two dosages because one half or one third of the dose may be quite as effective as the larger amount used.

We are all familiar with the treatment of pernicious anemia with liver and effective substitutes for use perorally and parenterally and no doubt also with the particular benefits of the use of intramuscular injections of a highly concentrated and uniformly potent liver extract, such as we have had the privilege of using at the Peter Bent Brigham Hospital for more than 4 years. I need not, therefore, attempt to discuss this form of treatment in detail but rather will limit my discussion to a few points which may be of practical value to you.

Inasmuch as liver in some form is a specific means of controlling the important features of pernicious anemia, and because it is necessary to continue adequate treatment indefinitely in order to control all phases, the importance of making a definite diagnosis before treatment is started cannot be too strongly emphasized. Diagnosis may be difficult in some instances before treatment has been carried out, but afterwards it may be quite impossible to make a positive diagnosis

except by allowing the blood to relapse, which is not a desirable thing to do. In addition to the cardinal signs and symptoms, one must consider the prompt and striking increase in the number of reticulocytes following the institution of liver therapy as a most important help in diagnosis. With the possible exception of sprue, there is no other condition in which this phenomenon occurs. In consequence of this, if there does not exist sufficient evidence to make a diagnosis, reticulocyte counts should be made sufficiently often during the ten day period following the institution of known potent liver therapy so that the presence or absence of a rise can be demonstrated.

The value of the reticulocyte-rise has been definitely established as a diagnostic aid when a liver substance of known potency is given to a patient with an anemia of questionable type. In like manner, the importance of this procedure must not be underestimated when used to demonstrate the presence of anti-anemic potency of a substance used in the treatment of a patient known to have pernicious anemia. The use of the determination of the magnitude of the reticulocyte-response as a means of evaluating the relative potency of highly active extracts for parenteral administration cannot be considered logical for reasons which have previously been demonstrated. Perhaps the most important evidence opposed to such a procedure is that comparable reticulocyte-responses may be produced by amounts of material entirely dissimilar as to their content of antianemic potency as judged by the erythrocyte producing power. Tests carried out on this basis will favor the extract of lower potency.

It can hardly be doubted that it is important to recognize the various amounts of potency available in the several substitutes for whole liver, which have been used from time to time. Until it was recognized that potency was lost during the production of peroral liver extract from liver, many patients were treated inadequately. The introduction of liver extracts for parenteral use made possible the administration of definitely controlled amounts of potent substance, thus enabling the physician to control the patient's intake more generally. Perhaps of even greater importance to both the physician

and the patient has been the availability of a concentrated liver extract which is of such uniform and high potency that small amounts of the substance injected intramuscularly will produce rather amazing results. As has been demonstrated previously, the injection of an amount of extract, 9 to 12 c.c. prepared from only 300 to 400 grams of liver, is sufficient to produce a maximal rate of erythrocyte formation and to produce a normal blood level in most instances within a 6 to 7 week interval. The normal state of the blood will be maintained with infrequent injections of 3 c.c. or the amount derived from 100 grams of liver.

After over 4 years of use, the practicability of treatment with a highly concentrated and potent liver extract injected intramuscularly is becoming more and more widely recognized, so that now the trend both in Europe and in this country is toward greater concentration of the material and toward conservation of potency, so that this simple and efficient treatment, which has been such a boon to the patient with pernicious anemia is becoming more and more widely used.

One might naturally expect therapy, which is not only the simplest but also the most efficient type, also to be the most expensive one. Interestingly enough this is not the case, but rather it is the least expensive of all. Compared with ingested whole liver the expense averages slightly less, and the difference in ease of use is tremendous. Liver extracts for peroral use are invariably much more ex-

pensive and generally an inconvenience for the patient. The possibility of infrequent as opposed to frequent injections, necessary with the use of extracts of low concentration or potency, together with the consequent reduction in expense, commends the use of the highly concentrated extract. The encouragement of any system of testing for potency or of treatment which fails to recognize the medicinal and economic benefits to the patient of the more highly concentrated and efficient extract, must be considered as a handicap to progressive medicine.

In closing I wish to emphasize the importance of an adequate intake of liver substance in the control of the disturbance resulting from sclerosis of the posterior and lateral columns of the spinal cord, treatment not only sufficient to maintain the blood in a normal state but also to supply an excess of liver substance. My experience during a ten year period indicates that with such treatment, there is no progression of pre-existing sensory or locomotor difficulties, that these do not begin during such treatment, and that there is improvement of some degree in essentially all cases. The amount of improvement will depend upon the extent and duration of the damage to the cord, but may be as high as 90 to 100 per cent. Although adequate amounts of liver substance in any form will accomplish these results, optimal amounts are best supplied by means of parenteral therapy.

311 BEACON STREET

NEW APPLIANCE TO COMBAT GANGRENE

A new appliance designed to combat gangrene has been installed by the Strong Memorial Hospital in Rochester. It is made by the Taylor Instrument Companies in Rochester, in collaboration with Dr. Louis G. Herrman of Cincinnati, and is the only one in use east of that city. It is called "Pavaex" and consists of a control box and a pair of giant boots made of pyrex glass. The boots come well up over the patient's knees and fit snugly around the thighs with soft rubber cuffs.

The control box houses mechanical and electrical equipment which alternates air pressure with a vacuum. As the vacuum is created, the feet, visible through the transparent glass, appear to increase in size and the veins swell.

When the pressure is applied they return to normal.

The machine has been used in Cincinnati for various leg circulatory troubles. Doctor Herrmann reported "of 14 patients given intensive treatment because of actual beginning gangrene or impending gangrene, all developed sufficient circulation to stop the progress of the gangrene and prevent its appearance in those cases where it was impending."

Harry Frank in his *Working North From Patagonia* gives the information that the doctors in Buenos Aires collect an admission fee at the office door.

CHRONIC APPENDIX SYNDROME

CHARLES F. TENNEY, M.D., F.A.C.P., *New York City*

"Chronic Appendix Syndrome" was purposely selected as a title for this article instead of "Chronic Appendix" because chronic appendix is a term too limited to express the true picture of what the extent of the involvement may be in the lower right quadrant. Aggregate symptoms associated with the morbid process and constituting together the picture of the disease are many and variable. I hope I may be able to present a picture which we have gleaned in the study of these cases over a period of five years.

Let us first consider the anatomy and the nerve supply of the right lower quadrant. There are certain facts which must be taken into consideration in arriving at a correct diagnosis. The first is that the terminal ileum, the cecum, and the appendix are capable of a certain amount of mobility and are normally not fixed in this area. It must be remembered also that the normal appendix is relatively uniform without constrictions and has a patent lumen which should allow the appendix to empty its contents the same as any normal portion of the tract. Semi-solid intestinal contents enter the appendix and may pass a partial obstruction where they lose some of their moisture and are then too solid to pass out the way they entered. They remain and become fecal concretions. Should constriction occur in the appendix these conditions may be intrinsic as from localized constrictions or extrinsic as from angulations due to a shortened mesentery or peritoneal adhesions to the appendix. The result is the same in either case. Not infrequently an appendix lies free of adhesions in the abdominal cavity and is completely and uniformly obliterated. Adhesions and membranes such as a Lane Band or Jackson Membrane have received scant consideration, although they are fully as important in the production of chronic symptoms. We believe some of these bands and membranes are congenital in origin, although a certain percentage are from former inflammatory processes. The cecum may be so involved that it has become completely

fixed. The adhesions may extend up over the terminal ileum to such an extent as to limit its mobility. They rarely cause actual obstruction and the symptoms they set up are doubtless reflex in nature. Their tug on the intestine gives rise to afferent impulses which spread to the sympathetic ganglia and interfere with the normal peristalsis, causing stagnation of the intestinal contents and constipation; or progressing still further set up a spasm in the pylorus, giving rise to gastric disturbances, such as pylorospasm. Adhesions involving the appendix alone can set up such reflex disturbances. The nerve supply in the appendix, cecum, and terminal ileum is both intrinsic and extrinsic. The extrinsic nerves are from the vagus and sympathetic. They carry both afferent and efferent fibers and are chiefly regulatory in their function. The sympathetics pass to the semilunar ganglion which also sends fibers to the stomach. This point must be borne in mind because of the close relationship between the sympathetics on the part of the stomach and the right lower quadrant.

In a recent article on "Abdominal Pain" Alvarez states that

if the present day understanding of a dual sensory nerve supply to some parts of the intestine is correct, the physician when faced by the common problem of chronic pain and soreness limited to the right lower quadrant should absolutely refuse to think of appendicitis and should look more for disease in the peritoneal attachment of the cecum. Theoretically, if smouldering disease in the appendix can produce pain anywhere, it should be felt where it commonly is felt, around the naval or in the epigastrium. Another reason for the radiation of appendiceal pain to the epigastrium may be that the function of the stomach, duodenum, and small bowel is disturbed secondarily to disease in the region of the right iliac region.

This, briefly, is the anatomical and pathological background with which the syndrome of chronic appendix is associated. Because of the varying type and degree of symptoms presented by the mass of patients referring to an indefinite

or vague lesion in the lower right quadrant, we are prone to attach the diagnosis of chronic appendix as a blanket diagnosis, realizing that in a large percentage this will be proven true by removal of the appendix.

In another large group the removal of the appendix *per se* will have had no influence upon the symptoms, and it is this group of cases which directs our attention to the necessity for a thorough investigation of all cases with symptoms which could be referred to as chronic appendix. In the main the symptoms presented by this type of patient have been present over a long period of time. There are periods of remission in the syndrome during which the patient has been perfectly normal. History of an acute attack of pain in the lower right quadrant, which may have been referred to as an acute or sub-acute appendiceal colic, may or may not be given. At some interval and for no apparent cause, or perhaps through some indiscretion in diet, vague gastrointestinal symptoms occur, which cause the patient considerable discomfort but not sufficient for him to consider himself acutely ill. Nevertheless, it is at this stage, probably because the vague and annoying symptoms persist, that he begins to seek medical advice.

Usually there is complaint of epigastric distress two to three hours after meals. This may be characterized by eructations of gas and hyperacidity, and frequently with marked intestinal flatulence, associated with constipation more often than with normal bowel movement or diarrhea. Some loss of weight is associated with these attacks. A nervousness which may be associated with or have preceded the attack is nearly always present. Pain in the right lower quadrant, which is usually among the first symptoms looked for by the physician, is in many instances now absent. Strangely though there may be complaint of discomfort in the right lower quadrant, actual pain is rarely encountered in this region in chronic appendix.

It is at this very point that the close association between chronic appendix syndrome and lesions of the pylorus should be mentioned. We have found that many a patient of the type described has pylorospasm in a mild form, but in many instances after persistency of symptoms ul-

cers actually occur which vary from the slightest mucosal inflammation to ulcers which have penetrated to the muscularis.

In all likelihood, a patient who thus presents himself for advice has previously had reported to him several different diagnoses and has had several kinds of therapy. What has been done may have been efficacious in the past, yet cannot relieve the present condition. It is then our problem to determine what etiological factor is producing this chain of symptoms. There are no exact rules in the approach to the solution. In order to present our concepts as to the method of approach in this type of case, it is necessary to describe what form of procedure we adhere to in these cases. These patients deserve the most careful consideration and a most detailed examination.

First, the physical examination of these patients should start with observation,—such as of the color of the skin, conjunctiva, and the floor of the mouth, also the absence or presence of rash or eruptions, and whether there are scars of previous abdominal operations. Secondly, the mouth should be examined. The color of the mucous membranes must be noted, and the tongue while it is protruded should be examined under an excellent light for change in the surface as to roughness or smoothness or coating. The teeth and gums should be carefully inspected for cavities or pyorrheal pockets to rule out a focus of infection. Pressure should be exerted on the tonsils to see if pus is present; at the same time the cervical region may be palpated for enlarged glands. In the examination of the thorax the chest should be palpated for any transmission of thrill, either from an enlarged aorta, aneurysm, or from increased vocal fremitus. Percussion of the chest should reveal whether there is any dullness at the right base, either as a lung or pleural involvement. Whether or not there are heart murmurs or friction rubs will be detected upon auscultation, and at the same time the chest should be listened to carefully for rales or for any increase in vocal fremitus.

Close abdominal inspection is important in ascertaining the condition as to distension, visible peristaltic waves, the presence of scars of former operations, and dilated skin veins on the abdomen. At first, pal-

pation should be done very lightly, though thoroughly to gain an idea of the general condition of the abdomen. This step, together with percussion, will betray any marked tympany, the presence of fluid, and enlargement of the liver or spleen. After this has been done deep palpation will help confirm the presence of tenderness or pain, enlargement of the liver or spleen, and any other palpable masses. Last but not least is the use of the stethoscope to gain information of the peristaltic activity. Rectal and vaginal examinations should be included to eliminate any possible pelvic pathology. The reflexes should be examined for any fixity of the pupils or absence of abdominal or patella reflexes. A urinalysis with particular reference to pus and blood must be included in the laboratory phase of the examination, having in mind the exclusion of a right ureteral calculus. Moreover, a complete bloodcount would be essential, particularly in betraying an early pernicious anemia with its bearing on a gastrointestinal disturbance. Similarly, a blood Wasserman must be done to obtain any clue that might point to early cord changes which through the central nervous system would give gastrointestinal symptoms.

If in carrying out this examination, symptoms point to a definite gastrointestinal disturbance, and it is apparently certain that these disturbances do not come from cord changes of diabetes, pernicious anemia, cerebrospinal lues or other diseases of the spinal cord, ureteral calculus, or a cystic ovary with a twisted pedicle, we now must verify our diagnosis by the demonstration of visible pathological changes by means of a complete x-ray gastrointestinal examination under the direction of a competent roentgenologist. What is the roentgenologist's definition of a chronic appendix? It is a controversial point which has been tossed to and fro between the clinician, the surgeon, and the roentgenologist for years, and it has not yet been agreed upon. I have searched the literature for a description of the findings in chronic appendicitis upon which a diagnosis of chronic appendix has been based from the radiological standpoint. The following description by a competent roentgenologist most nearly conforms with my own idea in regard to this point:

The diagnosis of pathology involving the appendix by means of roentgenological examination is fraught with danger. The majority of these examinations for appendix pathology are in patients whose symptomatology is vague or because of discomfort on pressure in the lower right quadrant. This comprises the main group, but there is another group in which the symptoms are chiefly gastric in character, yet the findings in a complete gastrointestinal examination indicate definite changes in the appendix and base of the cecum. We do not believe that there is any one finding upon which a diagnosis of chronic pathology of the appendix can be based. The appendix itself may show definite abnormal or pathological changes in the x-ray. Whether or not this is of the clinical type can only be determined by an evaluation of the roentgenological findings with the clinical symptoms. The presence of pathology involving the appendix and base of the cecum may be quite definite but not necessarily of clinical importance. Almost every patient of twenty years and above whose appendix has not been removed has had indefinite gastric or lower right quadrant symptoms at one time or another. If, in the course of a roentgenological examination, some abnormality of the appendix or base of the cecum is observed by the roentgenologist, it is apt to be interpreted in terms of clinical pathology by the physician receiving the report. With these facts in mind it is readily seen how difficult it is to make a diagnosis of clinical pathology in this region.

The x-ray findings which indicate pathology are: (1) Deformity of the base of the cecum, (2) changes in the lumen of the appendix, that is narrowing or dilatation, (3) fixation or angulation of the appendix, (4) retention of barium in the appendix after the barium has passed out of the cecum and ascending colon with or without a catharsis, (5) a fixed point of tenderness over the appendix observed during fluoroscopic manipulation, (6) reflex spasm of the pylorus when pressure is applied over the appendix—this is demonstrated fluoroscopically after the ingestion of barium.

The first four findings are due to morphologic changes involving the appendix and must be considered as such. They show that some pathology has been present. They may or may not be of clinical significance and must be correlated by the clinician with the symptoms displayed by the patient and the history of previous disturbances. The last two findings indicate some current change. Frequently the appendix is not identified filled either with a barium meal or a barium enema. By some observers

this has been considered evidence that the appendix is blocked off. It may mean an obstruction of the lumen of the appendix or the appendix may have filled and been evacuated between the examinations. It may indicate that there is complete obliteration of the lumen from atrophy of the appendix, and hence, of no clinical significance. It cannot be stated definitely which of these conditions has occurred.

Occasionally intestinal parasites are found in the lumen of the appendix, but it is by no means certain that they are the cause of the symptoms. Although not strictly a lesion of chronic appendicitis, mesenteric lymph adenitis should be mentioned. It may be part of a general process from tuberculosis or as a residual from the drainage of a previously infected appendix.

You will readily see our approach in dealing with the chronic appendix syndrome, viz., the correlation of the clinical observations, the laboratory findings, and the visible pathological changes shown in the x-ray examination. If chronic appendicitis is the disease, the cure comes through the removal of the appendix. If it is removed, opportunity should be given the surgeon for a complete and thorough exploration of the right lower quadrant so that not only the removal of the appendix may take place but a correction of any pathology which has occurred in and around the cecum and terminal ileum. It has always seemed to me that a very small incision handicaps the patient as well as the surgeon. It has truthfully been said that the surgeon can tell more accurately the clinical pathology of the appendix region and whether or not it has caused

symptoms than the pathologist can after the appendix has been delivered to him in the laboratory. The pathological reactions and the developmental anomalies in the adjacent tissues seem to us to be more responsible for the symptoms than the histological changes in the appendix. It has frequently been said that the pathological diagnosis of chronic appendix cannot be made truthfully. If that is taken to mean that such a diagnosis cannot be made on the histological evidence alone, there is much in the statement. It is usually impossible to differentiate the scar resulting from the previous inflammation from the fibrosis of normal atrophy. The presence of a few mononuclear wandering cells, plasma cells, or even occasional polymorphonuclear leukocytes has never seemed to me to be of much significance.

This then summarizes briefly our understanding of chronic appendix syndrome. The very chronicity of these cases makes it apparent that surgical haste should be tempered with judgment. There is no case encountered that requires more careful and detailed study and observation. It should be explained to these patients that the medical as well as the surgical treatment is important because they will require medical treatment both pre- and postoperatively. The promise of immediate cure by the removal of the appendix alone is far from true. A year may elapse before the complete disappearance of the symptoms even when the chronic appendix syndrome has been dealt with in a most efficient and careful manner.

FIFTH AVENUE HOSPITAL

DISTURBING WASSERMANN TEST DATA

Distinctly useful work has been found for some of the clerical workers on relief in Georgia by setting them to sorting and tabulating the mass of reports on file at the State Health Department relating to Wassermann tests during the years 1929-33. The findings are rather disturbing, and make one wonder what a similar investigation might reveal in other states, nearer home. There were over 200,000 reports in the accumulation, 136,000 of them stating the occupation of the patient. Running the eye down the resulting table, it appears that 10 per cent of the barbers and 31 per

cent of the manicurists examined showed positive reactions, not a very reassuring thought, while 30 per cent of all food-handlers examined, and 41 per cent of the cooks, revealed a like condition, which is still less conducive to peace of mind. Hospital attendants curiously show the same percentage as prisoners, 36, while nursemaids go one better, at 37. It must be remembered that the figures do not cover all the workers in these occupations, but only those examined, who may have been under suspicion, and the figures for all workers might be much lower.

PULMONARY ABSCESS

With Special Reference to Packing Treatment of Connors

THOMAS CIACCIO CASE, M.D., *New York City*

In the writings of Morgagni, of Van Swieten, and of Stoll one finds descriptions of cases of pulmonary abscess and gangrene. Boyle, however, first really published a description of the condition, he called it "Pulmonary Ulceration."

In 1818 Laennec described the pathological anatomy and clinical findings. He was the first to recognize pulmonary abscess as an entity among pulmonary diseases, but regarded it as an extremely rare lesion.

Later, men like Virchow and Fischer in attempting to clarify the nature of the disease found parasites in the gangrenous areas of the lung tissue, Traube and Detrick claimed that the putrefaction was due to a chemical property of the purulent debris which was stagnant in the bronchi. Leyden and Jaffee in 1866 called this offending parasite "*Lepothrix Pulmonatis*" and they thought it a variety of "*Lepothrix Buccalis*."

In 1875 Bucquoy described a pleuritic form, then in 1883 Landier published his work on pulmonary gangrene which complicated certain chronic affections of lungs and bronchi. Pasteur's work on putrefaction somewhat cleared the subject and he stated at the time, that putrefaction was brought about by the action of anaerobes. This contention was further supported by work of Veillon, Hallé, and others who found several species of anaerobes in the gangrene areas.

No form of treatment had been instituted until about 1897 when Skoda attempted to disinfect the gangrenous areas by inhalation of creosote. Later subcutaneous injections of eucalyptus were tried, but the treatment was mainly palliative and symptomatic in that it was simply attempted to alleviate the fetid odor and sputum, without regard for any effort being made to attack the gangrenous focus.

In 1875 Gluck, Mosier and Schmidt started to do research work on resection of ribs and in 1897 Tuffier first published his classical report on the indications and operative technic for pulmonary abscess and gangrene. Later, McKulitz (1905)

published many papers and statistics on the value of surgical treatment of lung abscess and in 1910 Picot reported on the accepted technic for the thoractomy as used today.

Artificial pneumothorax was advocated by Forlanini in 1918, but did not seem to have been accorded universal acceptance. There has been little progress made in operative technic, the best existing method being the two stage one for approaching the abscess with tube drainage.

In 1926 Dr. John F. Connors at the Harlem Hospital, New York City, first employed the method of tight packing for lung abscess. The first case operated upon was packed, not therapeutically, but for excessive bleeding and the packing was removed three days later, to reveal, much to his surprise, a clean granulating wound. Since then the method has been gradually perfected and all lung abscesses are now done when possible in one stage and packed with iodoform gauze at the Harlem Hospital.

Etiology

The predisposing causes of pulmonary abscess are (1) Lowered general resistance, (2) impairment or inhibition of the local defense mechanism, i.e., trauma or conditions which inhibit the activity of the cough reflex (anesthesia or coma) and the cilia of the trachea or bronchial mucosa (chronic bronchitis?), and (3) the presence of sufficient number of pathogenic organisms capable of producing suppuration.

The recognized causes in their apparent order of frequency briefly are:

(1) *Aspiration of Infection*. This seems by far the most frequent cause and statistics show that about 41 per cent of pulmonary abscesses develop following operative procedures and that about 80 per cent of the operative procedures were about the upper respiratory tract (Sixty per cent tonsils and teeth extractions). However, while aspiration of infective materials at tonsillectomy does occur yet as pointed out by Fetterolf, it is a mistake to regard this as the only or even necessarily the most frequent route. Lymphatic and blood vessels

are direct and potential channels of transmission from an infected and lacerated tonsil bed. Some of these postoperative pulmonary abscesses are undoubtedly of embolic origin.

(2) *Pneumonia*. Twenty-one per cent gave history of pneumonia from the start. Pulmonary abscess seems to be a relatively uncommon complication of lobar pneumonia, Hartwell at Rockefeller Hospital reporting only two cases out of 700 consecutive patients with pneumococcus lobar pneumonia. The relative frequency of abscess following bronchopneumonia is also uncertain, the cases probably being those of lung abscesses from the beginning and not recognized because of the difficulty in differentiating the pneumonitis concomitant with the early abscess and a pneumonic patch.

(3) *Embolic Origin*. Embolic abscesses may result from a pyemia or from infected thrombi originating in a thrombophlebitis, puerperal sepsis, or ulcerative endocarditis (3.9 per cent).

(4) *Extension of Infection* (3.6 per cent). An abscess underneath the diaphragm, such as in the liver, by perforating into the pleura of lung or by lymphatic extension may produce a secondary pulmonary abscess. At this point it should be mentioned that it is quite probable that lymphatic extension from foci of infection about the mouth is perhaps the cause for many of the lung abscesses which are erroneously diagnosed primarily as pneumonias or those in which the etiology is undeterminate. The high incidence of lung abscess in the mid-period of life is probably due to the fact that at that time we find dental infections most common. Children rarely have pyorrhoea of infected teeth, hence the low incidence of the disease in the first decade.

(5) *Trauma*. Blunt trauma from a blow, fall, or crushing injury may result in actual rupture of lung or more commonly in an interstitial ecchymosis and edema followed by pneumonitis and liquefaction with infection of the injured portion of the lung. Abscess following penetrating injury to the lung, such as stab wound, is due to devitalizing trauma to the tissue, but the infection may result in abscess long after the injury has healed. There are, however, very few of these because of the operative procedure followed in many of the stab wounds of the chest.

(6) *Specific Infections*. Under this heading are represented rare types of

infection producing pulmonary abscess, e.g., actinomycosis and infected echinococcus cyst.

Pathology

The pathology is of course determined in part by the avenue of infection, the type of infective organism, tissue resistance, and the duration of the lesion. Acute abscess may or may not be solitary, is usually spherical, miliary in size of up to 12 cm. or even more in diameter. The surrounding lung tissue may or may not show fibrosis early, the abscess cavity being recognized with certainty only by a fluid level. In other cases extensive pneumonitis is the outstanding characteristic in the roentgenogram. At this time two points should be stressed about the pathology, which are of paramount importance from the surgical aspect and those are: (1) Practically all lung abscesses are peripheral; (2) the pleura is involved and adhesions formed between the visceral and parietal pleura because of this fact. If the abscess is situated centrally, between lobes it is still peripheral, i.e., at the periphery of that particular lobe and in these cases the pleura may or may not be involved, but these cases are in the minority. These observations were noted by Tuffier in 1897 and have been corroborated by workers in New York City recently, e.g., Rabin at the Mt. Sinai Hospital.

The chronic abscesses are usually relatively large. The surrounding fibrosis varies in amount and extent and bronchiectatic changes in the communicating bronchi are often present. The longer the duration of the abscess the more fibrosis present and therefore this makes it much more difficult to heal when attempting to obtain a cure.

Diagnosis

In attempting a diagnosis it must be remembered that the history is of paramount importance. The diagnosis of pulmonary abscess rests on the determination of the etiology of the symptoms and signs and on the exclusion of other conditions giving rise to a similar clinical picture. The symptoms, of course, vary with the type and virulence of the infection, pathology present, patient's resistance and duration of the disease. In the prodromal

state, before the sputum becomes of characteristic odor, there are usually present malaise, chilliness and fever, with some increase in respiratory rate. After the abscess has been formed, cough with purulent foul sputum is the outstanding syndrome with associated symptoms of infection in varying degree. Foul sputum is more characteristic of abscess than of any of the conditions with which it may be confused. Hemoptysis may be an initial symptom.

Physical findings if present, are those of consolidation and cavity formation. An abscess that has not ruptured into a bronchus will show the signs of consolidation. Cavity signs occur only after the abscess has emptied itself in whole or in part by perforating a bronchus.

In chronic abscess the symptoms vary greatly in their combinations and severity according to the extent of involvement, degree of absorption, and the presence or absence of complications.

It is often difficult to differentiate an encapsulated interlobar empyema, from a pulmonary abscess or abscess with secondary empyema. However, if a very careful history is obtained and a careful study of the x-ray made (i.e., sharp localization of interlobar septa of empyema and presence of fluid level in abscess) and the character of the sputum noted, the differentiation should not be very difficult.

In attempting to localize the abscess, bearing in mind always that it is peripheral, the most important aids are (1) X-ray, and (2) physical signs. The x-ray will usually demonstrate the presence of a localized area of pneumonitis and often the presence of a cavity with air and a fluid level. The importance of obtaining lateral views of the suspected lung cannot be too strongly stressed. On palpating the suspected area usually the center of the area of flatness is chosen and often this area is found to be tender to palpation because of the presence of pleural adhesions.

Bronchoscopy and lipiodal injections are also resorted to, but not frequently. The bronchoscope is always used in cases where the presence of a foreign body in a bronchus is suspected.

Diagnostic aspiration through the intact chest wall cannot be too strongly

condemned. It may lead to false conclusions and to serious, if not fatal, complications, i.e., infection of clean pleural cavity or chest wall phlegmon.

Treatment

The principal objection to surgical treatment per se is the high mortality attending its performance, but very likely this is apt to be exaggerated as a consequence of the treatment. Too, it is apt not to be remembered that the disease itself is a serious one and that most patients have thoractomy performed many months after the onset of the abscess.

Some cases of lung abscess are cured by postural drainage. Bronchoscopic aspiration has proved its worth. When it is obvious that these cases are not cured spontaneously or by the use of the bronchoscope, they should be submitted for surgical intervention and at not too late a date. Even in the hands of a competent bronchoscopist the most that can be obtained is aspiration and washing out of the cavity, however, he cannot collapse the cavity, nor can he establish complete and adequate aeration and drainage of the cavity, both of which are quite necessary in order to effect a cure. (Bacterial anaerobes.) One must also keep in mind the possibility of spilling the fluid contents of the abscess into another part of the lung during the operation.

Collapse therapy, (i.e., the production of pneumothorax) is dangerous therapeutic procedure that should be avoided in all but unusual cases (Bleeding or central abscess). In the majority of cases the pulmonary infection extends to the periphery of the lung, in which instance adhesions between visceral and parietal pleura occur early. These adhesions not only interfere with an optimum collapse of the lung, but any tension on them is likely to tear the underlying necrotic lung, resulting in the production of a severe empyema, then again the presence of fibrous tissue about the abscess usually prevents the collapse of the cavity and it often happens that the mouth of the cavity becomes closed, causing retention of cavity contents and the condition becomes aggravated. (Used once in bleeding of abscess.) Therefore surgery is resorted to (thoractomy and packing) as the method of choice for treating lung

abscess, which method conforms to the fundamental requirements of complete and adequate drainage. The best time to operate unless untoward complications arise in the interim, is about six weeks after onset of the disease; (1) because within that time the patient will have been given the opportunity to heal spontaneously (10 per cent get well), (2) sufficient pleural adhesions will have been

saline is started before the operation and continued throughout the operative procedure. The patient is placed in a position most suitable for the approach to the abscess cavity. The incision, 3 or 4 inches long, is made in the direction and over the rib which crosses the center of the area of flatness. About 2 inches of the rib is resected subperiosteally and the underlying tissue is palpated and in-

Fig. 2. Incision in endothoracic fascia.

Fig. 5. Two ribs resected and cavity adequately exposed, then packed tightly.

formed, (3) in case of longer delay the infection may become overwhelming to the patient or other pathologic changes incident to a prolonged suppurative process might develop.

Procedure

The patient is anesthetized by using avertin and ether, and an infusion of

spectated. If the tissue feels indurated and there is no movement of the lung with the respiratory movements it is fairly certain the abscess is underneath, in which case the one-stage operation can be carried out. If there is doubt, the endothoracic fascia is carefully incised with a sharp knife and observation is thus then made certain. If the free

pleural cavity is opened at this point packing is inserted and a secondary operation performed at a later date (one week)

If the localization is correct then an aspirating needle is inserted into the cavity, putrid pus or foul air may be obtained, and a groove director is plunged in alongside of the needle. The opening is gradually enlarged until it admits the examining finger in order to palpate the extent of the pathology. If the cavity extends upward, part of the rib above is removed, or if it extends downward the same is done below so that adequate drainage is obtained. The intercostal muscles together with the intercostal vessels are ligated on either side and removed *en masse* in order to make the approach clear. If adhesions forming communicating intrapulmonary cavities exist, they are broken down in order to form one cavity. The cavity is then sponged until clean and iodoform gauze is packed into it rather firmly. The skin wound is laid wide open with packing and wound edges protected with vaselined gauze and a dry dressing placed over both.

If during the operation the clean pleural cavity should be opened accidentally the abscess cavity is packed with the iodoform gauze and the entire pleural cavity is picked off with plain gauze.

Postoperative Care

Fluids are forced and given by clysis if necessary. The patient is maintained on a high caloric diet, including whiskey, particularly to those who are habitual drinkers. Transfusions have been used freely, particularly in the cases which showed varying degrees of collapse. The patient is propped up in bed and is encouraged to get out of bed as soon as his condition allows and to move about and get out of doors when the weather is favorable. The packing is removed in 3 to 5 days, although most commonly on the fourth day, the abscess cavity then presenting a clean and even elastic appearance with the bronchial openings clearly in view.

The initial tight packing breaks down the abscess cavity membrane containing bacteria, pus, and fibrinous exudate. After the first dressing the abscess cavity is again packed but not as firmly as the

initial packing. This is repeated every other day and the wound allowed to granulate from below upwards.

After the cavity has been cleaned and healthy granulation tissue formed the large open wound is no longer necessary. It is allowed to close but not too quickly for quite often it may be necessary to relieve retention of toxic products and in order to prevent this and to get adequate drainage the opening should be about a half inch in diameter.

The orifice should be maintained open for a period of at least 4 months and then allowed to close only after an x-ray check up and the general condition of patient indicate certain cure.

The advantages of the packing method for lung abscess are many as Dr. Connors showed in 1931.

1 The abscess cavity is cleared early, within 3 days, and can be maintained as such until a cure is obtained.

2 Postoperative care is facilitated, i.e., frequent dressings are not necessary, and close attention to details is obviated.

3 Introduction of tubes is not necessary, therefore a source of pleural irritation is removed, and the possibility of osteomyelitis of ribs obviated.

4 The large thoractomy wound permits perfect inspection of the pathology and operative field.

Summary

1 Treatment of acute lung abscess is preferably surgical. It should provide early, complete, and adequate drainage of the abscess, the Connors method of packing conforming to these underlying principles.

2 With proper co-operation of x-ray and internist the one stage operation is most often possible and is the procedure of choice.

3 An atypical pneumonia should make one suspicious of beginning pulmonary abscess if the history is at all suggestive.

4 It is quite probable that lymphatic extension from foci of infection in the mouth is perhaps the etiology of many lung abscesses erroneously diagnosed primarily as pneumonias or those in which the etiology is undetermined.

EDITORIALS

A Retrogressive Trend

Since the war the annual matriculation at medical colleges has shown a progressive increase which threatens to undermine the important reforms accomplished by the Council on Medical Education of the A.M.A. From 18,200 in 1925, the number of medical students has grown to close to twenty-three thousand in 1935. This figure is not far removed from the enormous enrollments of the early part of the century.

An increase on this scale, which is not justified by any public need, must inevitably entail an impairment of the standards of medical education. Matriculates are chosen with less discrimination and the student body falls short of the scholastic and personal level achieved by more restricted admissions. Fortunately, the number of schools has not kept pace with the growing matriculation and the colleges in existence are, on the whole, superior institutions; but their facilities are not equal to the sharp rise in enrollments.

Besides threatening the quality of practice, the increasing registration at medical colleges has serious economic implications. The nation already has more physicians than it needs or is able to support. To pour an ever mounting number of recruits into a field that is already overcrowded, is to destroy the prospects of

the new-comers as well as jeopardize those already established.

The root of the situation is of course economic. With a general drop in income from endowments and gifts, the schools are almost completely dependent on tuition fees. More pupils mean more money and standards of admission are sacrificed to financial stress. A permanent solution will not be found until the accredited medical schools of the country are placed on a stable financial basis and relieved of their dependence on student income.

Spread of Common Sense

The organized profession in this state has grounds for strong satisfaction in the way some of its major economic principles have taken root in the past year. The organization of approved panels for workmen's compensation work, from which the patient may freely select his own advisers, represents the triumph of a medico-economic formula long advocated by physicians. Plans are now under way in a number of cities to use these same panels for home medical relief and professional service under various other projects.

In New York and many other municipalities in which both project physicians and the principle of home medical week have been tried, the latter arrangement

has definitely demonstrated its superiority. It is efficient, economical and approximates the normal American mode of life. In addition, it makes every dollar for medical relief do full duty by distributing available funds among the profession as a whole instead of a few favored practitioners.

The creation of the approved panels required under the Workmen's Compensation Act was an enormous task. Now that they are ready for use, there is no reason why they should not be employed for other undertakings in which the patient does not bear the financial responsibility for medical care. The examination of needy school children, the inspection of food handlers, the treatment of the indigent sick, the administration of preventive measures, can all be accomplished economically and well by certified private practitioners. Physicians and professional societies in every community should do their utmost to secure the application of this principle to appropriate medical programs.

Immunity Against Influenza?

By combining the public health control of communicable diseases with the more specific measures aimed at conferring active immunity upon susceptible individuals many of the epidemic diseases have been shorn of their morbid propensities. The incidence and gravity of diphtheria, typhoid fever and small pox have been reduced to a minimum by the precautionary measures of vaccination and preventive inoculation. The prevention of scarlet fever by immunization is still a problem for solution, since approximately ten per cent of those immunized will show a positive Dick reaction within one year. The committee appointed by the British Medical Association to investigate the efficacy of the various agents utilized for the purpose of immunization recommends the reservation of the latter procedure for compact groups of children wherein a case of scarlatina has developed and for hospital workers who are in contact with this disease. As regards

measles, all that can be hoped for at present is the establishment of a passive immunity by the injection of convalescent blood or serum.

For limiting the spread of epidemic encephalitis lethargica, poliomyelitis and the dread Spanish influenza, we have had to depend until now upon the strict enforcement of public health measures. Nevertheless, the epidemiology is contributing step by step toward eventual elimination of these ailments as a menace to community life. Laidlaw, Smith, Andrewes, and Dunkin¹ have recently reported their success in obtaining a potent anti-influenzal serum by hyperimmunizing horses with emulsions of virus obtained from ferrets infected with this disease. Not only does this serum confer certain degree of passive immunity to mice, but it also exhibits a decided therapeutic value in mice already infected. Prof. W. C. Topley² ventures to predict that the day is not far off when immunization of the human against influenza will become a reality. The transitional period between the experimental aspect of a medical problem to the stage where the new knowledge can be utilized practically, is always a long interval. However, the intense scrutiny with which science studies every new advance, before the general public is appraised of its worth and permitted to utilize it, is a necessary precaution for the protection of the public. This first step toward immunization against influenza deserves notation.

Cardiac Surgery

During the development of surgery as a means to cure disease it was only natural that the most rapid advances should be made, first, in the removal of structures whose usefulness had been destroyed and whose continued presence

¹ Laidlaw P. P. Smith W. Andrewes C. H. and Dunkin G. W. Influenza: preparation of immune serum in horses and Influenza experiments on immunization of ferrets and mice. *Brit. J. Exper. Pathol.* vol. 16 p. 275 and 291 June 1935.

² *J. A. M. A.* p. 608 vol. 105 Aug. 24 1935.

in the body threatened life. Later, refinements were devised for the repair of structures to establish their return to normal function. The field of surgery has been enlarged enormously by the rapid additions of new scientific discoveries until now it has reached a stage where it may be employed to treat virtually every organ in the body.

It has exceeded even its own bounds, since many diseases, formerly wholly in the therapeutic domain of the internist, have been conquered by the progress of surgery. The heart alone seemed to have escaped the zest of this surgical advance. The interior of the heart could not be attacked without extreme danger to life and the cardiac musculature with its terminal blood supply appeared as barren territory not worthy of surgical endeavor.

Nevertheless, it appears as if this very hopelessness has served as a stimulant rather than a deterrent to investigation. In the recent issue of *Surgery, Gynecology and Obstetrics*,¹ Beck briefly outlined the remarkable work that he and his associates are performing. They have succeeded in bringing a new blood supply to the heart muscle and have been able to

keep the musculature viable and the animal alive after occlusion of both coronary arteries. The injection of dyestuff into the surgically constructed extracardiac vascular bed found its way into the myocardium which became diffusely stained.

They have likewise operated upon four patients suffering from coronary occlusion with distinct beneficial results in three of the cases; the fourth died from another cause. It might seem at first that a report based upon so small a number of cases should not be commented upon by us, but the reason for our comment is best explained by Beck's own statement. "It was my desire to withhold presenting this work until the results of the operation as applied to patients were definitely known. Unfortunately, this was not possible. The operation is not without hazard and it is my sincere hope that surgeons will not accept and apply this operation to human patients until the results are known." With this conservatism we are in accord, yet the potentialities which both the laboratory work and the clinical material furnish, point a pathway whose direction is distinctly toward a new horizon in cardiac surgery.

MEDICAL RADIO BROADCAST

The Medical Information Bureau of the New York Academy of Medicine announces the following radio addresses to be broadcast from Station WABC and the Columbia Broadcasting System network:

Thursday, October 3, 1935, 1:15 P.M.
Speaker: Dr. Shepard Krech, Assistant Visiting Surgeon, Bellevue Hospital. Subject: Appendicitis.

Society Activities

Workmen's Compensation Committee

In answer to a query from the Chairman of the Compensation Board of one of the County Societies, the following letter was sent. Attention of all County Societies is called to this description of the basis on which "qualifications" can rest.

September 9, 1935

Dear Doctor ———:

I am answering your letter of August 28th in the absence of Dr. Heyd, who is still away on vacation.

In general, it should be the purpose of the various county societies, or their compensation boards, to qualify physicians in accordance with their education, training and experience. It would seem that nobody is as able to pass on a man's qualifications as his fellow practitioners in the community in which he practices. Judging by your letter, it would seem to me that Dr. ——— has been properly qualified by you. It is manifestly impossible to designate every possible specialty in which an individual has had some experience. The designation X (general practitioner) is all inclusive. It is taken for granted that a well trained practitioner has had more or less experience in the various specialties, but he should only be designated as having had special experience in a given specialty, and a letter in that specialty given to him, when it is recognized that he has had more experience than the average practitioner in his locality in that particular branch. For example, a general practitioner may possess physical therapy and even x-ray apparatus. The mere fact of possession, or some knowledge of the use of such apparatus, does not justify designating the individual with the special letters for Roentgenology or for Physical Therapy. If these letters are given to him, they should imply, as they indicate, that the possessor has had both training and experience in these fields beyond that possessed by the average practitioner in his community. The fact that the X man is not designated as, for example, M (1) Physical Therapy—in no way limits him in the use of physical therapeutic agencies on his own patients.

It seems that Dr. ——— has had special training in roentgenology and in physical therapy, as indicated by his memberships in special societies, and his own statement regarding his range of practice in these fields. In regard to his request to be listed under A and B, which letters would indicate that he is both a surgeon and an orthopedic surgeon, the mere fact that the doctor occasionally treats a surgical or orthopedic case, does not justify the Qualifying Committee of the County Society in designating him as especially qualified in surgery and orthopedics unless, in their judgment, his training and practice warrant it. Nobody is in a better position to elucidate this point than your Board.

As you know, the Industrial Council, the Commissioner of Labor, and the members of this Board are desirous of simplifying the designations as far as possible. When a specialist or physician insists upon numerous designations he actually confers upon himself the status of a general practitioner because it is unlikely that a man is especially skilled in numerous branches or has the necessary contacts in these numerous fields, to warrant numerous special designations. There should be a sharp distinction between a man in general practice with a major activity in one or two specialties, and those specialists who confine their practice to a limited field. It is unnecessary to give to the average general practitioner the designation of every branch in which he has had some experience and treats an occasional case, because under the law it is taken for granted that a general practitioner may do what his experience (and conscience) dictates without giving him a large number of designations. On the other hand, a specialist should, so far as possible, limit himself to his specialty because in general it is this restriction of work which implies and indicates that he possesses special qualification, skill, and experience. Of course here, too, preliminary training, experience and local custom must be taken into consideration in awarding the letter of a specialty.

I may say in general, that different communities must necessarily have different standards for the designation of specialties. For example, in New York County, most of the general surgeons, who undoubtedly occasionally see an orthopedic case, have not been awarded the special designation "B" unless their training and hospital connections are such as would indicate active association with special orthopedic work, and vice versa. This is eminently fair, because the well trained general surgeon is considered competent to treat the average surgical condition without the designation "B," and does not ordinarily, or usually, treat such orthopedic surgical conditions as require the special knowledge and technical skill of the orthopedic surgeon. Conditions in a smaller community may well require the general surgeon to embrace both fields in his work, and if in such community a general surgeon actually takes care of orthopedic cases in his routine practice, and especially in his hospital practice, he should be given both A and B designations.

Conditions differ in smaller counties where the number of especially trained physicians is limited, and the range of specialties is also limited. It is quite conceivable that in a smaller county a surgeon or general practitioner may have a major activity in, say Roentgenology or Physical Therapy; and if properly equipped to do this work, should be given the special designation on the basis of his training and experience, and the absence of a specialist to render this service to the community.

I hope I have made myself clear on a rather difficult subject. In closing, I may say that it is my belief that the local Board of the County Society, especially if advised by a special qualifying committee consisting of physicians in the

various branches of medicine, is the best agent to qualify the physicians of its own community and do justice to all concerned.

Sincerely yours,

DAVID J. KALISKI, M.D.

2. "Peripheral Vascular Disease." (Illustrated with lantern slides.) G. deTakats, M.D., M.S., F.A.C.S., Chicago. Peripheral Circulatory Clinic, Northwestern University. Discussion by L. Maxwell Lockie, B.S., M.D., Buffalo.

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

The International Assembly of the Inter-State Postgraduate Medical Association of North America will be held in the beautiful Masonic Temple, Detroit, Michigan, October 14, 15, 16, 17 and 18, 1935, with pre-assembly clinics on Saturday, October 12 and post-assembly clinics Saturday, October 19, in the Detroit hospitals.

The Association through its officers and members of the program committee extends a very cordial invitation to all physicians in good standing in their State and Provincial Medical Societies to attend the Assembly. An unusual clinical and didactic program including all branches of medicine and surgery and the specialties has been arranged by the program committee.

In cooperation with the Wayne County

Medical Society and the Michigan State Medical Society and with the active support of the Detroit Convention and Tourist Bureau and the Detroit Board of Commerce, a most excellent opportunity for an intensive week of postgraduate medical instruction is offered by a very large group of acknowledged leaders in the profession.

Registration fee of \$5.00 admits all members of the profession in good standing.

DR. CHARLES H. MAYO,
President, ROCHESTER, MINN.

DR. GEORGE CRILE,
Chairman Program Committee,
CLEVELAND, OHIO

DR. WILLIAM B. PECK,
Managing-Director,
FREEPORT, ILL.

Address: "The Diagnosis and Treatment of Surgical Lesions of the Pancreas". Dr. Irvin Abell, Clinical Professor of Surgery, University of Louisville School of Medicine, Louisville, Ky.

Address: "The Diagnosis and Management of the Septic Appendix". Dr. W. Wayne Babcock, Professor of Surgery and Clinical Surgery, Temple University School of Medicine, Philadelphia, Pa.

Address: "Surgical Treatment of Gall Stones". Dr. Frank H. Lahey, Director of Surgery in the Lahey Clinic; Surgeon to the New England Baptist Hospital and New England Deaconess Hospital, Boston, Mass.

"Doctor, I have caught a hard cold from getting too warm dancing the rumba."

"That is very common now, madam. I call it rumbago."—*L'Illustration, Paris.*

Patient: "I'm dreadfully nervous. I've never had an operation before."

Nurse (reassuringly): "You needn't feel

frightened ma'am. Neither has the doctor."
—*Dental News.*

A man in southern Nebraska who was recently haled to court and fined for practicing medicine without a license had been practicing, off and on, it was found, since 1877.

County Societies

Albany County

SOME OF THE "INSIDE FACTS" of European lands which are not permitted to go out on the cables, are brought back by Dr. Joseph Cohen, of Albany, who has just returned home after completing his medical studies at the University of Berne. He traveled all over Europe in vacations and after graduation, and reports great distress in Germany from lack of proper food and clothing. Criticism of Hitler is said to be open and growing. Dr. Cohen reports an epidemic of typhoid in Rome which has been kept quiet, and he says he found the people in every country wishing they could emigrate to America. The common people of Italy were "heart and soul with Mussolini," but expressed an "astonishing aversion to war."

DR. JOHN G. COPELAND, medical director of Albany Hospital for the past 10 years, has resigned, to attend the Graduate School of Medicine of the University of Pennsylvania at Philadelphia.

THE ALBANY COUNTY MEDICAL SOCIETY held its annual outing and clambake at Picard's Farm, New Salem, on September 11.

Dutchess County

A COMMITTEE OF PHYSICIANS to organize the Medical Society of Dutchess County was appointed at a meeting at the Amrita Club in Poughkeepsie on September 11. The medical men of Dutchess and Putnam counties formerly joined forces in one organization called the Dutchess-Putnam Medical Society. Now the society must obtain a new charter from the secretary of state changing its corporate name because of withdrawal of Putnam County members who have formed their own society. The Putnam County group, comprising about 10 physicians, received a charter last July.

On the committee on reorganization are Dr. A. L. Peckham, Dr. John R. Ross, Dr. Howard P. Carpenter, and Mayor Spratt, counsel to the society. The Dutchess County organization has 155 members since withdrawal of the Putnam County group.

Kings County

DOCTORS TAKE too little active interest in government, Supreme Court Justice Albert Conway told the members of the South Brooklyn Medical Society at their annual dinner. Especially in the matter of health insurance.

"This subject is of vital importance to all of you," he declared, "yet you are content to sit back and argue the matter among yourselves, but do nothing in the line of informing your Representatives in Congress as to your opinions and wishes."

SURGICAL INSTRUMENTS believed to have been used at the autopsy on the body of President Abraham Lincoln on April 15, 1865, the day after he was shot by John Wilkes Booth, have been presented to the Medical Society of the County of Kings by Dr. William Browning, professor emeritus of neurology at Long Island College Hospital.

New York County

MORE DOCTORS are badly needed to help check the spread of social diseases, as revealed in the records of the Women's Court, Magistrate Jonah J. Goldstein, who recently completed a term there, is quoted as saying:

"I record regretfully that the City of New York is not doing its duty in checking the spread of certain diseases. The problem is with us. The city has the power, but apparently is lacking in the social vision and the will. The records disclose that over 75 per cent of those brought before this court are health menaces. The city's attitude in handling this problem is best evidenced by the fact that only one part-time doctor is assigned to this court and that the chief of the bureau employed by the City of New York to handle this huge problem is on a part-time basis. In many cases not even the names and addresses of the prisoners are checked. Not until this becomes a full-time job, and not a part-time job, will we get anywhere in checking this health menace. It is high time that we treat the cases in the Women's Court as a medico-social problem." Because only a part-time physician is assigned to the court, Magistrate Goldstein said, offenders are often turned loose without any physical examination.

IN ORDER that consumers may know what kind of vitamin D milk they are receiving, the New York City department of health has recently issued regulations requiring complete information to be printed on the caps of bottles. This must include not only the method that has been used in fortifying the milk but also the number of units of vitamin D per quart. The board has fixed the following minimum vitamin D content

for the three kinds; if produced by feeding irradiated yeast to cows, 430 units per quart; if produced by direct irradiation with ultraviolet rays or carbon arc ray lamps, 135 units; if produced by the addition of concentrate, 400 units. Physicians should give instructions as to which kind of vitamin D milk they wish their patients to receive, the health department bulletin suggested.

MARIHUANA TRAFFIC in New York City has been dealt a staggering blow through a cooperative campaign for its control conducted by police and health departments.

Samples of the marihuana plant (*cannabis sativa*) also known as hashish, bhang and loco weed, were sent by the Division of Narcotics of the police department to various precincts throughout the greater city of New York, so that detectives and patrolmen might become familiar with the leaf. Instructions were issued to these men to report at once to the Narcotics Division any areas in which plants resembling marihuana were found. Upon definite identification of the suspected plant, the Narcotics Division reported the facts to the New York City Department of Health which had all growing plants torn up by the roots. During June and July, 260 lots were cleared of 170 tons of marihuana, including root and stalk, by relief labor.

In addition to areas adjacent to New York City, marihuana has been discovered as far north as Waddington, close to the St. Lawrence river, and as far west as Erie county, suggesting that it may be grown almost anywhere in New York State.

Onondaga County

DR. J. G. FRED HISS, Dr. Jane Sands Robb and her husband, Dr. R. Cummings Robb, all members of the Syracuse University College of Medicine faculty, were awarded the bronze medal of the American Medical Association for outstanding research at the annual conclave of the association in Atlantic City, N. J.

The Syracuse scientists were honored for their joint research, conducted more than 10 years, on heart muscle-bundle physiology and experimental coronary lesions. Their research is regarded as opening a new approach in the treatment of coronary thrombosis.

The medal was the third highest in the division of Class One exhibits of the association, awarded on the basis of originality and excellence of presentation of individual investigation.

Dr. Jane Robb directed the research, mak-

ing her first report on it three years ago at a meeting of the Syracuse University Medical Alumni Association here. Besides designating anatomical names for five heart muscles she had discovered in her research, she presented what was regarded as a highly important explanation of the electrical action of heart muscles.

With the aid of her husband and Dr. Hiss, Dr. Jane Robb experimented with the hearts of cats, dogs, pigs, bulls, sheep and monkeys. In these animals she was able to produce artificial coronary thrombosis by tying off one of the heart muscles, according to a report she made last April before the Federation of American Societies for Experimental Biology at Detroit.

By charting action of heart muscles on an electrocardiograph recently acquired by the College of Medicine, the scientists determined which of the heart muscles are affected when coronary thrombosis sets in.

DETAILS ARE being worked out for a "three-cent-a-day" hospital plan in Syracuse, with a probable start late in the fall, according to Carl P. Wright, superintendent of the General Hospital.

Queens County

THE HOUSE COMMITTEE of the Auxiliary of the Queens County Medical Society is furnishing a new board room for the medical society in the Medical Building, Forest Hills. The auxiliary voted a considerable sum of money at the close of the season for this purpose. Mrs. Carl Boettiger is chairman of the House committee. She is the wife of Dr. Carl Boettiger, Flushing, chairman of the 2nd district.

Seventh District

A MEETING of the physicians of the Seventh District was held in the recreation hall of the U. S. Veterans Hospital in Canandaigua on September 26. The chief topic of discussion was infantile paralysis. Morning and afternoon sessions were held, with luncheon, inspection of the hospital, and a visit to the Sonnenberg gardens.

Headed by Monroe County with 778 members, and Ontario County with 72 members, the district organization is made up of representatives from Cayuga, Yates, Steuben, Wayne and Seneca Counties. Officers are Dr. Alfred K. Bates of Auburn, president; Dr. Thomas W. Maloney of Geneva, first vice-president; Dr. Howard A. Barsted of Hornell, secretary, and Dr. Edward T. Wentworth of Rochester, treasurer.

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Restraint of Unlawful Practice of Medicine

The problem of satisfactorily combating the unlawful practitioner of medicine, is always before us in one form or another. The method in which such a situation was handled in a neighboring state forms the subject of a case* recently before its highest Court.

The statute regulating the practice of medicine in that State, is in general similar to the New York statute, and forbids any person to practice medicine and surgery within the State without a license from the State Public Health Council. The statute makes medical practice without a license a misdemeanor and provides penalties for such offenses. It seems that a certain M in one of the larger cities of the State, had been for several years engaged in treating numerous persons for various ailments and infirmities, undertaking to make diagnosis and prescribe treatment, all for a monetary consideration. He had referred to himself in newspaper advertisements, according to the charges in the case, as Dr R B M and had described his office as "M— General Health Center."

One of the duly licensed physicians who practiced his profession in the same city, in order to put M— out of practice, brought a suit against him in the Chancery Court for the purpose of enjoining the defendant from practicing the profession of a physician and surgeon in the State without a license. The proceeding was instituted by the plaintiff "for the benefit of himself and all other physicians similarly located." The bill in Chancery which set forth the complaint, included the charges above referred to and a declaration that the practice of the profession is not a common right, but a privilege obtained by virtue of a public grant in the nature of a franchise and that the plaintiff and other licensed practitioners have an interest similar to a property right entitling them to equitable relief in the form of an injunction against encroachment thereon by an unlicensed person in order to prevent the continuance of the irreparable injuries caused by such conduct.

An application was made by the defendant to the Trial Chancellor to test the

sufficiency of the charges by a demurrer. The Trial Chancellor sustained the defendant and the matter was taken for review to the Supreme Court of Appeals of that State. That Court reversed the ruling of the Chancellor and held that the charges presented a prima facie case for equitable relief in the form of the injunction sought by the plaintiff.

In the opinion, the Court for a precedent, laid particular stress upon a case involving the illegal practice of law.** In that case, a licensed attorney had brought a similar suit to enjoin a corporation from practicing law by hiring attorneys to carry on the work of the practice of law. The opinion in the latter case was quoted in part as follows:

The right to practice law is an exclusive valuable privilege, exclusive in that it is restricted to those who, after special training and after examination and determination of special fitness, are accorded the right to follow the profession of attorneys and counsellors at law, and valuable, in that it carries with it the opportunity to secure material benefits and to earn a livelihood not given to those outside the profession. This right is in the nature of a franchise, and a practicing attorney at law and others similarly situated have such an interest as members of the legal profession in the nature of a property right, as will support the authority of such attorney at law to proceed as a proper party in an action to secure equitable relief against encroachment upon such right by a corporation.

In its opinion the Court cited several statements from other cases in support of the proposition that the right to practice a profession is a valuable property right entitled to protection by the courts, which included the following:

The right of a person to practice the profession for which he has prepared himself is property of the very highest character.

The right to practice medicine is like the right to practice any other profession a valuable property right in which, under the Constitution and Laws of the state, one is entitled to be protected and secured.

The right of a physician to toil in his profession as well as that of all other citizens to labor in their chosen work is both liberty and property, partaking of the nature of each, and

* Sloan v Mitchell, 168 S E 800

** Dworken v Apartment House Ass'n, 176 N E 577

is guaranteed by constitutional mandate from unwarrantable interference.

The argument was urged before the Court by the defendant that since the acts complained of amounted to charges that the defendant had been guilty of a crime, no injunction should be granted, but that proper procedure would require prosecution of the defendant on criminal charges for whatever crime, if any, he had committed. The Court, however, refused to give support to the contention, and ruled that the case was a proper one for injunction even though the same charges might form a basis for prosecution in the criminal courts. In so holding the Court quoted the following in support of the ruling:

It is freely admitted that equity will not enjoin the commission of a crime as such, as, for instance it will not enjoin one from carrying concealed deadly weapons or from committing any other crime whether it be a felony or misdemeanor, where nothing else is involved except the commission of the crime; but where the chief purpose of the statute is to provide for the public welfare by regulating (not prohibiting) some already lawful calling and only provides a penalty for refusing to comply with such regulations, and which penalty is enacted as a punishment for such refusal, we can discover no logical reason why a court, in administering the laws of its jurisdiction, would be powerless to prevent the doing of the prohibited act merely because a penalty (only nominal in this case) is attached for a refusal to comply with the regulation.

Death Following Novocaine Injection

A physician who specialized in nose and throat work, was consulted by a 21 year old girl who complained of throat trouble. The doctor found that she was suffering from a peritonsillar abscess. He treated the condition and it cleared up, but since her

tonsils were enlarged and diseased he advised their removal as soon as her condition permitted.

A few months later she returned to his office and was ready for the operation. The doctor seated the patient in a chair and examined her pulse, heart, and lungs; found them to be functioning normally and decided that she was a safe subject for novocaine. Using a sterile needle and syringe, he proceeded to inject 10 c.c. of novocaine for the purpose of anesthetizing the field of the operation. Just as he injected the first charge of novocaine under the anterior pillar of the patient's right tonsil, she stiffened up in the chair and fell forward. The doctor picked her up and felt for her pulse, but could find none and was unable to hear her heart beat. He poured whiskey down her throat and gave her artificial respiration. He also called in another doctor from an adjoining office who assisted him in his attempts to revive the patient, but the attempts were unsuccessful.

The novocaine which the doctor had used, he obtained from some bottle from which he had taken novocaine administered to several other patients with no ill effects. An analysis of the solution failed to disclose any reason why it should have caused any unusual reaction in the patient. An autopsy was performed upon the patient by an assistant medical examiner, who gave the following cause for death: "Shock following novocaine injection for local tonsillectomy."

An action was brought by an administrator, charging the defendant with having wrongfully caused the death of the patient. A conference was held with the plaintiff's attorney when the case was called for trial, before the Judge and the plaintiff consented to discontinue the action, thereby acknowledging that he was unable to prove the doctor had been guilty of malpractice.

PROFESSIONAL SECRECY TO SHIELD CRIMINALS

British criminals, it appears, find it much safer to have their injuries patched up by a doctor than the American bandits do. The Chairman of the Central Ethical Committee of the British Medical Association recently made the following ruling, which has been approved by the Council of the Association:

"A request by the police to a member of the medical profession to give the names and addresses of any patients who had consulted him for symptoms particularized by the police ought to be declined, on the ground that to accede to such a request would be a gross breach of professional

confidence and might involve him in an action for damages by the patient or patients concerned."

A monument to the "Unknown Dog" was unveiled in Leningrad on August 8 at the Institute of Experimental Medicine. The inscription on the monument, bearing the stone image of a dog, reads: "In memory of all dogs which have given their lives for physiological experiment for the purpose of prolonging human life and improving human health."

Across the Desk

YEAR BY YEAR the chiropractors, naturopaths, and manipulators of all sorts keep hammering at the doors of the state legislatures for recognition, and year by year the medical societies are put to considerable expense and effort just to keep before the lawmakers' minds the simple fact that healing the human body should be entrusted only to those who know something about it. The almost comical claims of some of these cults is illustrated in the bill to license chiropractors that came before the Massachusetts legislature this last session. It not only permitted chiropractors to treat disease by adjustments of the spine, but forbade anybody else to do so! It defined chiropractic as follows:

"The system, method or science, commonly known as chiropractic, or the practice of chiropractic, is defined to be the science of spinal examination; the adjusting of the segments and the articulations of the human spinal column by hand only. This definition is inclusive and any and all other methods are hereby declared not to be chiropractic."

Then in another section it provided that anyone not registered as a chiropractor who practiced this "science or system" should be liable to a fine of \$50 to \$500 or a jail term of 30 days to one year. If the English language means anything, this bill meant that if a duly registered physician examined a single spine by eye or hand he could be sent to molder in jail for a year—two spines, two years. Of course the bill did not pass, but what a light it sheds on its authors. Their examination might well start at a point just north of the spine.

Looking over the trend in recent years, two things stand out. One is that a large number of States are permitting the practice of "drugless healing." The other is that more and more knowledge is being required of those allowed to register under such acts. If these requirements are raised higher and higher by intelligent public demand, it may be possible in time to compel all who practice the healing art to have first a complete medical education. Anything less is a peril to the people's health and life.

"Drugless healers" are now licensed in California, Illinois, Indiana, Kentucky, Michigan, New Jersey, Ohio, Pennsylvania, Virginia and Washington. The practice of naturopathy is regulated specifically by law in Arizona, Connecticut, District of Columbia, Florida, Oregon, South Carolina and Utah. If we examine the new Arizona statute, we find that the naturopath must have a high school diploma, and must have

studied four years in a school of drugless therapeutics, with the following number of hours on the following subjects:

Anatomy, including dissection, 650 hours; histology and embryology, 150 hours; physiology, 250 hours; chemistry, 200 hours; bacteriology, 100 hours; pathology, 350 hours; diagnosis, including physical, clinical, x-ray, symptomatology, dermatology and mental diseases, 500 hours; orthopedics, 100 hours; manipulative and adjustive technic, 200 hours; dietetics, 200 hours; drugless gynecology, 150 hours; non-surgical obstetrics, 150 hours; toxicology, 50 hours; first aid, 50 hours; ear, nose and throat, 50 hours; hygiene and sanitation, 100 hours; jurisprudence, 45 hours; drugless therapeutics, including electrotherapy, physiotherapy, hydrotherapy, massage, and practice of naturopathy, 750 hours; clinical practice, 300 hours, and such other subjects as the board may require, excepting materia medica and major surgery, with a total not less than 4,500 hours. An applicant must pass an examination given by the basic science examining board in anatomy, bacteriology, chemistry, hygiene, pathology and physiology.

The thought that rises very naturally to the mind is: Why not spend more time and study and have a thorough medical education? Then the practitioner can heal with or without drugs, as he wishes, but he will at least have an adequate understanding of the human organism under his hand.

A GOOD POINT was made the other day by a doctor who was speaking over the radio about psychiatry. The patient, he said, should get rid of the feeling that a stigma attaches to mental illness. "The proper attitude," said Dr. Irving, "is to consider all mental disturbances on a par with ordinary illness," and "there should be no more sense of shame or guilt over a neurosis, or an 'insanity', than over an attack of appendicitis."

There is a lot of common sense in that statement. Mental upsets, in these nerve-racking times, are often caused by influences totally beyond the patient's control, and no blame of any kind can be laid at his door. The finer his personality, the more he feels the hammer-blows of misfortune. His neighbor, with a nature about as delicate as that of an ox, has no call to look down on him. Change the man's circumstances, or change his outlook towards them, and his storm-wracked soul will right itself to an even keel.

The wrong one, in fact, is sometimes brought to the psychiatric clinic for mental examination. The wife is brought when it is

the husband who should be locked up, and vice versa. A doctor in a New York mental hospital remarked not long ago that he often felt when a little child was brought for correction treatment that the parents were the ones who needed it most. Many an actual case is on record where the stealing, lying, screaming, fighting child is sent to live with grandma or Aunt Kate, and miraculously returns to normalcy and happiness.

We are but children of a larger growth, and our mental troubles, too, may not be of our making. Yet we tend to hide them from the gentle questioning of the psychiatrist because we fear some stigma that is entirely in our imagination. The doctor can do nothing for the patient who is covering up and concealing the facts, and Dr. Irving is right when he says that honesty and frankness are the first requisites for recovery.

In the same way, irreparable harm is done by people who conceal diseases that carry a moral stigma. Society seems to ignore blandly the fact that such infections may be contracted innocently. A medical journal recently recorded a case where four members of a family contracted syphilis in various ways from a young daughter who had acquired it from an outside source. First, she gave her chewing gum to her little brother; then she chewed some bread to a soft pulp and fed it to the baby. The baby, in nursing, infected the mother, who in turn infected the father. Four innocent victims. And it became known only when the father and mother accused each other of infidelity and appealed to the doctor. He found out the truth and saved the home.

Women who suspect malignant growths sometimes shrink in terror from telling the doctor, and conceal the scaling and thickening spot on the skin, or the pigmented mole, or other manifestation that calls aloud for instant help, till too late. The State Department of Health is running a series of articles in *Health News* on various types of cancer, with special reference to signs, character of growth, and treatment, to aid the physician to recognize it early enough for successful treatment. But very often it is the patient who needs the education, needs to learn the great lesson of confiding in the doctor and telling him the truth, the whole truth, and nothing but the truth.

Pages, in fact, could be written on the harm done just by hiding away the little ills of the body and mind till they become big ills. If some bright young advertising man should write a slogan like "Little ills make little bills," and broadcast it appropriately on the billboards, it might catch the spirit of the times, so that people might

heed the call of dollars and cents where the appeal of common sense is now ignored.

A SERIOUS DISCUSSION has been going on for some months in the pages of the medical journals over the question: "Shall we tell the cancer patient the truth?" The very fact that the profession is debating the subject shows that it is rearranging its ideas and questioning its own former attitude. Has the time come when honesty is the best policy? The American Society for the Control of Cancer thinks that it has. In its bulletin it points to the extensive educational efforts in recent years to give the public the facts about cancer, and suggests that deception and subterfuge by the physician at the very time when cancer becomes an actuality mars and damages public confidence in all that has been taught. The fear of cancer is almost universal, and if people feel that they cannot depend on their own family doctors to tell them the truth, then fear degenerates into panic. The laity have been educated up to the point, however, where they are using their intelligence rather than their emotions, and they expect and should receive frank and intelligent treatment from their physicians. The enlightened attitude of the laity is leading to early treatments and to more cures, and this splendid state of things should be fostered and encouraged.

Sweden has for years had the settled policy of informing cancer patients of their true condition as a routine procedure. Of course, delicacy and tact are often used in breaking the news, but eventually all are told. Swedish doctors agree unanimously on the wisdom of this course. The average citizen, they find, fights more intelligently and persistently when he knows what he has to face. Morale is high in both doctor and patient. Diagnosis is rapid and accurate. Treatments are prompt and well-attended. In short, the situation is in shining contrast to other European lands where ignorance and fear darken the picture and hamper successful treatment.

Every rule has its exceptions, and the bulletin of the American Society for the Control of Cancer admits that in exceptional cases or peculiar situations it might be best to keep the patient in ignorance. That is for the physician to decide. But taking the public by and large, the feeling of those who have been closest to the educational campaign is that the laity have matured sufficiently to hear the truth and that to continue a policy of deception may result in the collapse of much already achieved.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits or in the interests of our readers.]

Clinical Tuberculosis Edited by Benjamin Goldberg M D Two volumes Fully Illustrated with over 640 Half Tone and Line Engravings and 9 Full Page Color Plates Octavo Philadelphia, F A Davis Company, 1935 Cloth, \$22 00

The Spleen and Resistance By David Perl's M D & Jessie Marmorston M D Octavo of 170 pages Baltimore, Williams & Wilkins Company 1935 Cloth, \$2 00

The Diseases of the Endocrine Glands By Hermann Zondek, M D Third edition Octavo of 492 pages, illustrated Baltimore Williams & Wilkins Company, 1935 Cloth, \$11 00

A Textbook of Clinical Neurology with an Introduction to the History of Neurology By Israel S Wechsler, M D Third edition Octavo of 826 pages, illustrated Philadelphia W B Saunders Company, 1935 Cloth, \$7 00

The Surgical Clinics of North America Volume 15, number 3 June, 1935 (Chicago Number) Published every other month by the W B Saunders Company, Philadelphia and London Per Clinic Year (6 issues) Cloth \$16 00, Paper, \$12 00

Mental Health Its Principles and Practice

with Emphasis on the Treatment of Mental Deviations By Frank L Howard, Ph D & Frederick L Patry M D First edition Octavo of 551 pages illustrated New York, Harper & Brothers, 1935 Cloth, \$3 50

Nutrition Work with Children By Lydia J Roberts Second edition Octavo of 639 pages, illustrated Chicago University of Chicago Press 1935 Cloth, \$4 00

Methods and Materials of Health Education By Jesse F Williams, M D & Fannie B Shaw, M A Duodecimo of 331 pages New York Thomas Nelson and Sons, 1935

Arthritis and Rheumatoid Conditions their Nature and Treatment By Ralph Pemberton, M D Second edition Octavo of 455 pages illustrated Philadelphia Lea & Febiger, 1935 Cloth, \$5 50

The Autonomic Nervous System Anatomy, Physiology and Surgical Treatment By James C White, M D Octavo of 386 pages, illustrated New York The Macmillan Company 1935 Cloth, \$7 00

REVIEWED

The Study of Anatomy Written for the Medical Student By S E Whitnall M D Second edition 12mo of 93 pages Baltimore, William Wood & Company, 1933 Cloth \$1 50

The University of Bologna claims to have furnished instruction in human anatomy for a thousand years In consideration of the length of time that the subject has been taught, its instructors have been surprisingly inarticulate as far as printed discussions of methods of studying and teaching are concerned Articles on these subjects are confined almost exclusively to the last three decades and there are not many of them in this period A census of the number of articles more or less completely devoted to advances in the knowledge of human anatomy now appearing suggests that about one hundred thousand have been published during this same interval of time

Whitnall's brochure, which now is in its second edition is almost unique, if we except introductions to a few manuals of anat-

omy, in that it is addressed to the student rather than to the teacher It illuminates in vivid paragraphs phases of anatomical study both in the laboratory and in the library The student is counselled to disassemble the body into its many parts only that he may gain a picture of it as a united mechanism He is urged to exercise his powers of discrimination between the important and the unimportant, as much as to utilize his capacity to memorize facts and principles It is shown that the laboratory offers the one opportunity in his lifetime to fix in a leisurely manner gross anatomy in his mind by sight and touch and that if he forsakes a stool and the cadaver for a chair and a book on anatomy, he is cheating himself

The book is too pithy to be completely absorbed in a sitting It should be returned to by the first year student from time to time It is doubtless destined to save many a beginner misdirected effort It also offers stimulating reading to the teacher

E D CONGDON

Manual of Clinical Laboratory Methods. By Pauline S. Dimmitt, Ph.G. Octavo of 156 pages, illustrated. Philadelphia, F. A. Davis Company, 1934. Cloth, \$2.00.

This manual will be useful to students, interns, and physicians doing clinical laboratory work. It cannot, of course, replace the larger standard reference works. There are chapters on examination of the urine, blood, sputum, gastric contents, feces, exudates, and milk. The bacteriological methods include agglutination tests and the preparation of vaccines. Standard methods for blood chemistry, blood transfusion tests, and the Friedman test for pregnancy are described. Under the Wassermann test the author describes the Kolmer, Noguchi, and Eagle modifications. She also describes the Eagle flocculation test for syphilis.

The directions are clear and concise and there are numerous illustrations.

E. B. SMITH

Brucella Infections in Animals and Man. Methods of Laboratory Diagnosis. By I. Forest Huddleson. Octavo of 107 pages, illustrated. New York, The Commonwealth Fund, 1934.

This volume, arising from the cumulative experience of seventeen years of work in Brucella disease by an acknowledged master of these diseases, is particularly authoritative. Brucellosis in man is a "coming" disease, a disease that belongs to the future. With each passing year more cases are being reported in the literature of types unlike the book descriptions of undulating or "Malta" fever, cases resembling encephalitis, neurasthenia, malignant types like typhoid, ambulatory cases resembling tuberculosis, subclinical varieties of short duration. The clinician would be unable to diagnose Brucellosis in many of these cases without the aid of laboratory tests. Huddleson in this monograph presents briefly and concisely the most accepted methods. After a short history of the three species, *Brucella melitensis*, *Abortus*, and *Suis*, he describes their morphology, staining and cultural characteristics. The methods of isolating the organism from cattle, from the milk of animals, and from the blood of human beings are carefully discussed.

Since it is now a well-established fact that all three species of *Brucella* are pathogenic for human beings, gaining entrance by way of the skin through contact with infected animals or by way of the mouth through ingestion of raw dairy products which contain the living organism, and since knowledge of the laboratory tests is of paramount importance in making a diagnosis of this disease, this book comes

quite opportunely and should be of interest not only to the veterinarian and research worker, but particularly to the physician.

H. S. BIKOFF

Definite Diagnosis in General Practice. By W. L. Kitchens, M.D. Octavo of 1000 pages. Philadelphia, Saunders, 1934. Cloth, \$10.00.

This is an ingenious compilation of symptoms and diseases devised in such a way that the busy practitioner can obtain an accurate diagnosis readily and easily. However it pre-supposes a thorough study of the patient and careful evaluation of symptoms and laboratory data for without this it can be seen how one would be easily led into error.

The book is divided into two parts. In part one each symptom, 506 in number, is listed at the head of a separate page and underneath are recorded the diseases in which this symptom occurs followed by the page number in part two upon which the disease is noted.

In part two, each disease, 407 in number, is arranged on a separate page and the symptoms that occur in the disease, both subjective and objective, and the pertinent laboratory data are listed below with the page number upon which these symptoms were noted in part one.

In this way the book can be used for quick reference to obtain all the important symptoms of a given disease. Or knowing the symptoms and pertinent laboratory data by listing the diseases in which they occur a diagnosis can be readily obtained.

This book can be highly recommended to the practicing physician and we are sure he will find it both interesting and stimulating.

ARTHUR E. LAMB

Hughes' Practice of Medicine. Revised and Edited by Burgess Gordon, M.D. 15th ed. Duodecimo of 808 pages illustrated. Philadelphia, P. Blakiston's Son, [c. 1935]. Cloth, \$5.00

This small *Practice of Medicine* used by students for many years in its earlier editions has been completely revised with numerous deletions in the sections on treatment and furnishes a condensed description of the usual picture of disease. Many new subjects are treated and there are quite full sections on Nervous and Mental Diseases and Diseases of the Skin. A helpful feature is a list, on the back cover of normal laboratory findings from Nicholson's "Laboratory Medicine."

It is a very useful book for general review or quick reference.

W. E. MCCOLLUM

PNEUMOTHORAX IN PNEUMONIA**An Appraisal**JESSE G M BULLOWA, M D, *New York City**Clinical Professor of Medicine, New York University Medical College, Visiting Physician,
Harlem Hospital*

Before attempting to appraise the value of induced pneumothorax in the treatment of the pneumonias it is pertinent first to state the local and general effects of pneumothorax, and next to examine briefly the factors which influence the pneumonias in respect to the severity of their symptoms and the outcome.

The physiological results of inducing pneumothorax have been carefully studied by many workers (Moore,¹ Törning-Coryllos and Birnbaum,² Means and Balboni,³ Fine and Drinker,⁴ and Bendove,⁵ to mention a few.)

Normally the lungs are vacuum attached to the interior of the thoracic wall. During inspiration the bronchi are lengthened, fanned and their walls pulled apart. In expiration these movements are reversed and the bronchi are shortened, contracted and approximated at their distal ends. By reducing the vacuum the lung may be collapsed and become airless or atelectatic. When the pleura is free from adhesions and is filled with air at atmospheric pressure, the lung ceases to expand and no air may enter the alveoli. Under these circumstances the circulation diminishes in the collapsed lung and increases in the uncollapsed lung but the total cardiac output is diminished.

When the lung is filled with exudate, as in pneumonia, normal movements are impeded or cease completely in the part

consolidated. Under these circumstances the circulation through the lung is diminished as has been shown by injection of the consolidated lung with radiopaque substance by Gross. In the collapsed lung the vascularization is ample through tortuous capillaries, as has been shown by Moore¹ and Adams, Hrdina and Dostal.⁶ Means and Balboni found that with one lung collapsed, ventilation was accomplished in a normal manner in spite of greatly reduced vital capacity. However, when extra demands are made, the limit of ventilation is reached sooner in persons with a collapsed lung than in normal persons. At rest and even up to a point when the respiration is trebled or quadrupled, the single lung will secure a normal gaseous exchange and carbon dioxide tension, if greater demands are made, the limit of capacity may be reached and then anoxemia develops.

While the lung remains attached to the thorax wall, the lower lobe rotates and moves forward with inspiration. When a good pneumothorax is induced, the normal forward and rotating swing of the lower lobe on the upper at the hilus is stopped and the movement and rubbing of pleural surfaces cease. However, the collapsed lung is not motionless, under the fluoroscope it may be seen to swing from side to side. The beneficial effects of pneumothorax in pneumonia are

*From the Littauer Pneumonia Research Fund of New York University and the Medical Service
Harlem Hospital (Department of Hospitals), New York City. This research received support
from the Metropolitan Life Insurance Company. Read at the Annual Meeting of the Medical
Society of the State of New York, Albany, May 15, 1935.*

alleged to be due to rest of the lung and diminished lymph circulation. Approximation and rubbing of pleural surfaces continues unless the expansion of the

chest is impeded by air in the pleura, by fluid pleural exudate, or by external pressure or strapping. Sling strapping the costal margin diminishes the forward swing of the lower lobe by impeding movement of the lower chest.

CHART I—FAILURE TO COLLAPSE EARLY PNFUMOTHORAX TYPE XV. POST MORTM X-RAY AFTER REMOVAL OF AIR DILIRIUM

Amount of Collapse and Local Effect

Aside from adhesions, the duration of the disease is not the only factor which influences our ability to collapse the involved lobe. The type of invading organism and the consequent character and amount of exudate are also important. Some cases of relatively short duration are not collapsed. In one case due to Pneumococcus Type XV, twenty-nine hours after the onset the lobe was so dense that it did not collapse appreciably (See Chart I.) This patient became delirious and orthopneic. Air was removed from the pleura at the forty-first hour, but he died in two and one-half hours. The postmortem x-ray examination in the sitting posture shows a dilated heart and an uncollapsed right upper lobe. When dense exudate has developed, the lobe involved cannot be collapsed and any effects on its intrinsic movements and circulation that might have resulted from collapse have already been secured without sacrifice of additional respiratory surface.

Recent recommendations of Blake are that a positive pressure shall be maintained in the pleura on expiration. This is not necessary for relief of pain. We have obtained relief of pleural pain after lung suction when the pneumothorax produced was too slight to be visualized by x-ray examination. With positive pressure, we occasionally observed a displacement of the mediastinum and in some cases, an emphysema of the chest tissues. When undertaking pulmonary collapse we cannot tell with certainty, either by the history, by pressure readings, by the amount of air accepted, or by previous x-ray examinations, the extent and nature of the adhesions which may be present, nor what part of the lung will be collapsed. The diseased lobe may not collapse appreciably if it is adherent (x-ray) but unless the uninvolved lung is adherent it will usually collapse to a greater extent than the lobe which is in-

flamed. Collapsed lungs may resolve rapidly, or more slowly than usual.

Results of Collapse

A collapsed lobe, already the seat of inflammation, may apparently become more involved, and a lobe which is not involved on the collapsed side may be involved. This happened twice, as exemplified in the following case.

B M entered on the third day. His left lower lobe was consolidated due to *Pneumococcus Type VIII* (See Chart II). The lung was well collapsed with pressure plus one plus three, on the sixth day the temperature rose and the left upper lobe was found consolidated while the lower lobe resolved. Both lobes cleared. There was a sterile exudate.

Secrecion may be expressed from the diseased lung into the lung of the opposite side and cause infection. Very early in the disease it may be difficult to determine that the opposite side is free from disease.

Usually the lung expands fairly promptly and additional air must be given to prevent re-expansion of the lung. Occasionally the lung shows no evidence of expanding, until air has been removed from the pleura.

Chest Pain

Chest pain in pneumonia is of two kinds. (1) pleural pain due to inflammation of the pleural surfaces with fibrinous exudate in the case of the *pneumococcus pneumonias* and early effusion in the *streptococcus pneumonias*, and (2) pain due to congestion and engorgement of the lung. The engorgement of the lung is associated with skin tenderness or hyperalgesia and fixation of the chest resulting from the heightened muscle tone of the involved myotome. Both varieties of pain are relieved by splinting the chest with adhesive plaster or by collapsing the lung. In the latter case, if too great pressure is applied, the pleura may become distended and cause severe precordial distress and at times abdominal pain. When there is positive pressure in the pleura, air may escape into the subcutaneous tissues (subcutaneous emphysema) and cause great or moderate local pain and tenderness. In our cases this occurred a number

of times, as shown in Table I. Sometimes the mediastinum is displaced.

Cyanosis

Early in pneumonia cyanosis occurs when areas of lung are blocked by exudate and when un-aerated blood mixes with the aerated blood. Under these circumstances, collapse of the lung shunts blood through the opposite side where it is adequately aerated if the demand for oxygen is not too great. Later in pneumonia the cyanosis if it occurs is due either to such extensive involvement of respiratory surface that aeration is inadequate, or to cardiac failure. This latter condition causes congestion of the lungs and inefficient aeration on that account. Such cyanosis has not been relieved by still further limiting the aeration area or by furnishing further embarrassment to the circulation by shunting all the blood through one lung, or part of one lung. Kinking or pressure on the great veins in the chest may interfere with the circulation. Under these circumstances the circulation is so embarrassed that orthopnea (uncommon in pneumonia) results. This occurred in two of our patients.

Factors in Prognosis

Before proceeding with an evaluation of pneumothorax in pneumonia, it is well to discuss the factors which determine the severity of the pneumonia and the rate of the pneumonia patient. Among the most important may be listed:

TABLE I

* Throbbing pain in one case. Anterior and posterior pain in one case.

1. The resistance of the patient, such as age and previous health or associated disease.
2. The kind and virulence of the organisms invading the patient and their number and, if a pneumococcus, its type.
3. The extent of the invasion with resulting loss of respiratory surface.
4. The occurrence of bacteremia and complications.

The resistance of the patient may be either (1) humoral, as may be readily seen in patients recovering from pneumonia when protective substance develops in response to stimulation of the invading germs, or when it is passively transferred from animals by treatment in administer-

CHART II

NOTE: Extension to upper lobe with positive pressure. Rise of temperature. Termination on 9th day.

ing serum, or (2) due to specific local resistance forming a lung-blood barrier. This local resistance has recently been studied by Tuttle and Cannon⁸ in experimental observations on dogs in the passage of bacteria through the lungs into the blood stream. They have studied the difference in blood invasiveness resulting from injections of suspensions of staphylococcus aureus, bacillus prodigiosus and streptococcus hemolyticus into the lower lobe of the lungs of fourteen healthy dogs. The hemolytic streptococcus immediately entered the blood stream. The other

organisms were either derived or did not enter it. Our own experience with the invasiveness of streptococcus hemolyticus is in accord with theirs especially after pneumococcus infections, and is exemplified in the case the report of which follows.

CW suffered from a Type IV pneumonia of his right lower lobe. After collapse of the lung, which was incomplete because of adhesions, a bacteremia supervened. This subsided after a number of days and the temperature and pulse reached normal. Forty-eight hours later, the temperature and pulse rose (See Chart III) and the blood was again invaded by *Pneumococcus* Type IV and streptococcus hemolyticus; the patient succumbed.

The experiments of Neufeld and Kuhn⁹ seem to have bearing on this ques-

tion. They showed that the administration of ether to mice made organisms usually non pathogenic in the mouse capable of producing fibrinous pneumonia.

The virulence of organisms hastens death and may be seen by the well known necessity when testing serum for potency of selecting organisms which are not too virulent. With my co worker, Miss Wilcox, I have shown¹⁰ that the virulence of the relatively avirulent chained organisms may be stepped up by repeated mouse passage and that they then lose their chaining. Stillman,¹¹ in 1930, showed that virulent pneumococci rapidly entered the blood stream of rabbits exposed in spray chambers while avirulent organisms were destroyed by pulmonary phagocytes.

Effect of Pneumothorax and Duration of Illness

Those who have studied the course of the pneumonias recognize not only the great similarities but also the marked differences in their course and duration. The natural duration of the pneumonias is shown in Chart IV for recovered cases who were treated without specific therapy for a number of types. It may be seen that sometimes the disease terminates early and sometimes late, and that for each type, there seems to be a special habit. Only when we have a sufficient number of cases of each type and study the distribution of the duration shall we be certain of the effect of this treatment on length of illness.

The pneumococcus type and the treatments are given in Chart V for our

CHART III—TERMINATED WITH STRIPTOCOCCUS HEMOLYTICUS BLOOD INVASION.

CHART IV—DAY OF TERMINATION OF RECOVERED NON-SERU

patients. We may say, however, that from the evidence in the literature and from the cases reported to us by others and from my own cases, that the duration of the diseases apparently has not been materially affected by pneumothorax therapy. Robertson agrees with this finding. Table II gives the day of termination of the disease in my cases listed by the day on which collapse therapy was initiated. It will be seen that the day of termination did not depend on the day of

induction but rather on the day when one would expect immunity. This is also shown in Table III which gives the manner of termination. Some of the cases terminated by lysis and some by crisis. Relatively few cases terminated in three days after induction of pneumothorax.

Effect of Character of Collapse

The character of the collapse did not affect the duration or promptness with which the disease terminated, as may be seen in Table IV giving the day of termination of cases with good, poor, and fair collapse. A patient with no collapse terminated promptly. Some patients with good collapse took longer to defervesce than some with poor or fair collapse.

Occurrence of Agglutinins

When the presence of agglutinins was studied, as in Table V it was found that they appeared at the times defervescence was expected and occurred. When de-

tested by our relatively crude methods, humoral immunity seems to go hand in hand with recovery. Cases who died did not develop agglutinins. One case had agglutinins on the first day and after therapeutic collapse, the temperature fell on the second day.

Bacteremia and Pneumothorax

The pneumococci of different types produce pneumonias which are quite distinctive in respect to the frequency of blood invasion. Invasion of the blood stream determines, to a large extent, the fate of the patient, and the successful treatment of pneumonia depends upon preventing bacteremia, and overcoming it when it is discovered. (It may be said in passing that it requires, at the very least, twelve hours to determine by cultural method whether the blood stream is invaded and many more to demonstrate that the blood was clear at the time the culture was taken.) The importance of bacteremia in causing death is shown for each important type separately up to Type XXII in Chart VI, which gives

the death rate in bacteremic and non-bacteremic cases. The possibility of preventing bacteremia with serum is shown for Types I and II.

Coryllos and Birnbaum have stressed the importance of bacteremia from experiments on dogs in observations hither-

to unpublished (to be given in the discussion). They found that the mortality rate closely paralleled the incidence of bacteremia.

In our cases, bacteremia was present five times before induction of pneumothorax and supervened five times after pneumothorax was performed. (See Table VI) (a) Of those in whom it was present prior to induction, three were Type II cases. Among the five Type II cases encountered, two developed empyema although treated with serum; one case not treated with serum died. The cases that recovered without serum were a Type VIII and a Type XXXII. Type VIII bacteremia patients relatively, frequently (40%) clear the blood stream spontaneously. Patients with Type XXXII have always recovered in our experience (b) Of the five cases who developed bacteremia after pneumothorax induction, one was a Type I nonserum case. He received pneumothorax on the first day. His bacteremia ceased spontane-

ously, and he became delirious. Because of pain, he left the hospital and was cared for at home. One had a *Pneumococcus* Type V. He received serum after he developed a contralateral lobe involvement. (This case will be narrated later in detail.) One was a Type IV who subsequently died with a concurrent streptococcus hemolyticus invasion. The other was a hemolyticus streptococcus pneumonia with subsequent abscess and meningitis. One was a patient with Type III. The lung was not collapsed but the mediastinum was displaced. She was overwhelmed by her bacteremia.

In our study of pneumothorax therapy, we selected only adult patients. Our experience with pneumothorax in children, as it occurs spontaneously or from trauma, has been that it does not affect the course unless it has been bilateral or was of the tension variety as occurred in a recent post-measles case when air had to be removed.

Pneumothorax and Toxic Symptoms

One of the claims made for the pneumothorax treatment is the reduction of toxic symptoms. In pneumonia, toxicity is a very difficult matter to gauge. Anoxemia competes with toxicity in producing symptoms. Most of the so-called toxic symptoms are associated with bacteremia. In our cases, certain symptoms occurred in what seemed more than usual frequency, especially in the cases which were not promptly terminated, as shown in Table VII of the occurrence of dyspnea, orthopnea and delirium. The delirium rate was greater than with serum. In Type I cases, delirium occurred in 18.5 per cent of non pneumothorax cases and in 40.5 per cent of all our pneumothorax cases.

Delayed effects of absorption were not mitigated, as shown in the case of E.M., who developed severe tubular nephritis.

TABLE VII
Therapeutically induced pneumothorax in 37 Cases

Symptom	Subsequent to Pneumothorax Induction					
	Appeared Cases	%	Increased Cases	%	None Cases	%

Cyanosis	11	29.7	1	2.7	25	67.6
Delirium	15	40.5	0	0	22	59.5

statistically significant. This has been demonstrated by us in the case of Type I and confirmed in Massachusetts and in England. We agree with Blake that pneumothorax has no effect on bacteremia. Delay to determine the presence of bacteremia before administering serum, causes the use of more serum than would have been otherwise necessary, and may even permit the patient to be overwhelmed.

We lost no cases of Type I pneumonia given pneumothorax although this may be attributable to the prompt use of serum, especially in the case of W.W., who had an invasion of the contralateral lobe.

W.W. 26 years, was admitted to Harlem Hospital with moist rales throughout both lungs and dullness with diminished breath sounds at the right base. His pulse was 136, respirations 44, and his temperature 104. His white blood cell count was 26,400; polynuclears, 85 per cent. X-ray showed a consolidation in the lower portion of the right lower lobe; the remainder of the lung fields were clear. The sputum revealed *Pneumococcus* Type I (Neufeld).

At 3 P.M. a pneumothorax was performed with the administration of 150 c.c. of air. A radiogram taken after this pneumothorax showed a slight amount of air below the consolidated lung. At 8 P.M. the temperature and pulse fell, the pulse being 114, the temperature 100 and the respirations 36. At 8 P.M., 375 c.c. of air was administered. The pressure reading changed from minus 5 minus 1 to minus 3 plus 1, and there was considerable relief of pain. At 11.45 P.M. an additional 425 c.c. of air was administered and the pressure readings were minus 4 plus 1½. During the night the temperature rose to 106 and the pulse, which had reached 130, was 118. Another radiogram, taken during the night, showed a well collapsed right lower lobe, a partially expanded right upper lobe and a definite involvement in the central portion of the left lung field. There were signs of consolidation in the upper portion of the left lower lobe.

The same may be said of the case of *Pneumococcus* Type V with contralateral lobe involvement (See Chart VIII).

F.P. came in with a pneumonia of his left lower lobe. On the first day of his disease this was found to be due to *Pneumococcus* Type V. He was not particularly ill. The lung was collapsed. There was no effect on the temperature or pulse. Next morning the patient complained of severe bilateral pain and marked dyspnea. The heart was markedly displaced to the right. 500 c.c. of air was removed from the left side with considerable relief, and a radiogram taken several hours later showed a marked involvement of the left lower lobe. The patient was markedly dyspneic and orthopneic even in an oxygen tent, and actively delirious. The blood which had been sterile became invaded. Very large and frequent doses of Type V serum caused the temperature to fall. Agglutinins ap-

peared in the blood stream, the pulse and temperature fell to normal and the lungs cleared.

The patient with Type VIII whose contralateral lung was infected was not severely ill and had a capacious chest. This was also the experience at the Hospital of the Rockefeller Institute where a Type VIII case became contralaterally invaded and recovered without serum. (Dr. Abernethy)

Evaluation

How shall we appraise the value of pneumothorax treatment of the pneumonias? Shall we use the results of treatment as a yardstick to compare the mortality with untreated cases due to the same pneumococcus type, or shall we compare the results with the best competing treatment? Shall we judge it by its effect on symptoms, or by its ability to overcome the great lethal factor in these diseases—bacteremia?

If one studies the literature, it is amazing to find the slim evidence on which pneumothorax is recommended. Coghlan,¹² whose report in *The Lancet* in 1932 is responsible for the present interest and which produced the recent contributions on this subject, reports six cases with one death. The charts are quite similar to many cases of unmolested pneumonia observed on our service with crisis on the fourth to the eighth days. In one case there was a death, and in one, crisis was attributed to the introduction of 10 c.c. of air.

Careful x-ray studies of the collapse of the lung, of the type and of blood invasion are lacking, nor is the diagnosis of pneumonia always clear-cut and adequately confirmed. Some writers, as David Li¹³ and Henius¹⁴ report the use of therapeutic pneumothorax in children and adults together, despite the very great difference in the mortality from the pneumonias in these two groups. Li reports as a favorable result, a case where pneumothorax was employed on the 16th day, and crisis occurred on the 18th. Klotz¹⁵ did not have a lobar pneumonia in his series and one of his four cases, a child of five, died. Groom and Gilbert's¹⁶ case was a tuberculous pneumonia. In the literature, only the cases of Blake have been adequately studied. Under date of April 29, 1935, he wrote me:

Of the eighteen Type I cases, six died (30%). All but one of these six cases were in the late fourth-day group. You will recall that we do not feel that pneumothorax treatment is of advantage as late as this in the disease. Three of these cases received Type I serum. The fatal cases on the last chart had a bacteremia at time of admission before commencement of treatment.

Among 239 cases of pneumonia due to *Pneumococcus* Type I treated at Harlem Hospital during eight years with serum and without pneumothorax on the fourth and fifth day of disease, there were 33 deaths (13.9%). At the Hospital of the Rockefeller Institute, two of their three Type I pneumothorax cases received serum, and all three patients recovered.* Patients alleged to be suitable for pneumothorax treatment by reason of earliness in illness, if they suffered from *Pneumococcus* Type I and were treated with serum, would have little or no empyema.

A great objection to the treatment of mild cases of pneumonia with pneumothorax is that the essential elements of the pneumonia problem are overlooked. Such cases recover in spite of reduced respiratory surface. Determination of type of pneumococcus by examination of sputum and blood should not be omitted or delayed by the physician who treats pneumonia.

On the immunity mechanism the mechanical collapse of the lung has no effect. Immunity can be given by serum. There is now serum commercially available for three different types of pneumococci. At least nine additional sera have been studied, and some give promise of value. These have been prepared by the Department of Laboratories of the Health Department, New York City, and studied through the additional generous support of Mr. Lucius N. Littauer, the Metropolitan Life Insurance Company and the Altman Foundation, Inc. The work is costly and results would be obtained sooner if more and better serum were available, but this requires additional financial support. The direction of pneumonia study should not be diverted from its present fruitful direction of securing

* Letter from Dr. T. J. Abernethy, Resident Physician, April 29, 1935.

means of protecting the blood stream from pneumococci, and clearing it after they are present. The fatality rate and the blood invasion rates are usually parallel. Whether cure of bacteremia is to be accomplished by sera or ferments is immaterial. The problem of pneumonia has not yet been made susceptible to a surgical maneuver but remains a problem in immunity, which requires trained careful clinical and bacteriological study and differentiation.

Summary

Pneumothorax induction immediately relieves severe pleural pain. This may also be accomplished by other methods and occasionally by such a slight pneumothorax that is not visible radiographically. This occurred ten times in a single year on the performance of routine lung suction for diagnosis among 400 patients. Pneumothorax may be induced accidentally as the result of lung aspiration without apparent change in the course of the disease. There is an ample margin of safety and with a capacious chest, one lung may provide sufficient surface for gas exchange. The relief of pain may be followed by oppression and soreness in the chest. Contralateral involvement may occur, or be present and in that case the pneumothorax increases the anoxemia. Displacement of the mediastinum may occur and require relief. Pneumothorax has no effect on the immunity mechanism

and does not prevent or cure bacteremia. The disease may not be shortened.

The symptoms of anoxemia are more frequent and more severe in some pneumonia patients with pneumothorax. The performance of pneumothorax does not absolve the physician from the responsibility of promptly determining the type of pneumococcus involved and the use of available specific sera of proven value to prevent and cure bacteremia. Early use of serum in pneumonias due to *Pneumococcus* Type I prevents empyema. The treatment is not one for the home, and while being evaluated should only be employed with x-ray guidance by those accustomed to pneumothorax therapy and its hazards and by those familiar with the pneumonias and equipped to study their problems.

Addendum

Six additional patients suffering from lobar pneumonia have received therapeutic pneumothorax with results essentially like those reported. Accordingly, our impression remains that though defervescence may occasionally follow induction of pneumothorax in pneumonia in many cases fall of temperature may have been a coincidence. To us it seems that inherent hazards outweigh the advantages alleged by advocates of the treatment.

The additional cases are briefly presented in chronological sequence. (See Table VIII) 62 West 87th Street

Discussion

DR. POL. N. CORYLLOS, *New York*—My contribution to the discussion shall be limited to the experimental aspect of this question, and to its relation to the pathogenesis of pneumococcus lobar pneumonia as I understand it.

Dr. Birnbaum and myself have studied the influence of artificial pneumothorax in labor pneumonia induced in dogs. A detailed report of this work which was carried on in the Department of Surgical Research of Cornell Medical College is about to appear in the Archives of Internal Medicine. I shall present only a brief resume of the results obtained.

Forty dogs were used. Lobar pneumonia was induced by the bronchoscopic technic devised and described by Coryllos and Birnbaum in 1929. Twenty to thirty c.c. of 18 hour old culture in broth of pneumococcus Type I were centrifuged and the sediment suspended in 1 c.c. of broth. By means of bronchoscope, the mouth of the bronchus of one of the lower lobes was located and the suspension was injected into it through a 2 mm. brass tube. In a number of animals the sediment was mixed with 1½ per cent agar or starch broth. In all cases intraperitoneal anesthesia was used (Amytal 55 mgm. per kilo. body weight).

Blood cultures were made of all animals. 24 hours after injection of the pneumococcus culture 2 c.c. of blood were taken from a peripheral vein and poured in agar plates. At autopsy as soon as possible after death cultures were taken from the heart.

Of the 40 animals used in that investigation 17 received pneumothorax (250-500 c.c.), and 23 served as controls. 3 were moribund and in coma 24 hours after-inoculation, and all 3 were bacteremic. 2 were left untreated and one received pneumothorax. All 3 died.

Six animals, 3 with and 3 without pneumothorax, died between the 30th and 112th day after inoculation; 4 of these animals were bacteremic at the start. Only in one of these 6 animals were gross pulmonary lesions found at autopsy.

A distinction should be made between the very toxic and the slightly toxic animals. 26 of the 40 dogs were very toxic and 14 slightly or not at all toxic. We gave pneumothorax to 15 toxic and 2 slightly toxic, and used 11 toxic dogs as controls, two of which were moribund, and 12 moderately or slightly toxic. This was done because long experience with experimental pneumonias has taught us that slightly toxic animals as a rule recover spontaneously. It was therefore interesting to submit dogs, with rather severe unilateral pneumonia, to pneumothorax treatment.

Our results do not corroborate the findings of the experimental work of Lieberman and Leopold. These authors obtained recovery in 15 out of 18 pneumonia dogs treated with artificial pneumothorax, whereas of the 18 untreated controls only 3 recovered and 15 died.

In our work, the mortality was not influenced at all by the induction of pneu-

mothorax; it ran parallel to the presence or absence of bacteremia.

Of our 40 animals 24 had negative cultures. Of them 21 (87%) recovered and 3 died (13%). On the contrary 16 had positive cultures, and of them only 3 recovered (19%) and 13 died (81%). (Table I.)

If now we consider more especially our 26 clinically toxic animals (Table II) we find that 12 had negative cultures and 9 of them recovered (75%) and 3 died (25%) whereas of the 14 with positive cultures only 2 recovered (14%) and 12 died (86%).

This shows that the incidence of bacteremia matched the incidence of mortality—40 per cent for both in the total number, and 54 and 57 per cents respectively in the toxic group.

Of the 26 toxic and perfectly comparable animals, 15 received pneumothorax and 11 served as controls. We purposely did not include the slightly toxic animals in order to deal with animals presenting clinically and bacteriologically comparable pneumonias (Table III). As we shall see, this was not done in the work of Lieberman and Leopold, which explains the apparent discrepancy between their results and ours.

Of this group 15 had pneumothorax; 9 died (60%) and 6 recovered (40%). Of the control animals 6 died (55%) and 5 recovered (45%). Consequently there was no marked difference.

A closer study of the influence of pneumothorax upon animals with and without bacteremia and a comparison of the results obtained in them with the results observed in the controls (Table IV), shows that of our 15 animals which received pneumothorax 7 were negative and 8 positive. Of the 7 negatives, 3 died (29%) and 5 recovered

TABLE I

*Incidence of bacteremia to incidence of death
(total group)*

Total Number	40	24 Negative—3D,* 21R (87% recovered, 13% died)	16 Positive—13D, 3R (19% recovered, 81% died)
Incidence of bacteremia	40%		
Incidence of death	40%		

* Died ** R—Recovered

TABLE II

*Incidence of bacteremia to incidence of death
(toxic group)*

Toxic	26	12 Negative—3D, 9R (75% recovered, 25% died)	14 Positive—12D, 2R (14% recovered, 86% died)
Incidence of bacteremia	54%		
Incidence of death	57%		

TABLE III

Incidence of highly toxic animals in pneumothorax and non pneumothorax groups

Pnx (15)	Moribund and very toxic (12 cases) Moderately toxic (3 cases)	Ratio is 4:1
No Pnx (11)	Moribund and very toxic (9 cases) Moderately toxic (2 cases)	Ratio is 4½:1

TABLE IV

14 slightly or not toxic at all
No Pnx—1 positive, recovered (12) 11 negative, recovered

TABLE VII

From Lieberman and Leopold—(*Amer J of Med Sc.* 187 315, 1934)

Table 2—(page 320)
Pneumothorax Dogs, that recovered (15 out of 18) (81%)

Blood Culture negative—9 60 0
Blood Culture positive—6 40 0

Table 4—(page 328)
Untreated Dogs that died (13 out of 18) (72%)

Blood Culture negative—4 30 0
Blood Culture positive—9 70 0

Of these animals 12 died within 3 days

(71%) whereas of the 8 positives, 7 died (87%) and only 1 recovered (13%). Of the 11 controls, 5 were negative and 6 positive. Of the former, only 1 died (20%) and 4 recovered (80%). Whereas of the 6 positive, 5 died (83%) and only 1 recovered (17%). Again we find that pneumothorax had no effect: these final results depended upon the presence or absence of bacteremia.

If we compare the incidence of bacteremia to the incidence of death in the pneumothorax and the non-pneumothorax groups (Table V) we find that in the pneumothorax group 7 of the 9 fatal cases had bacteremia (78%) and in the control group 5 of the 6 fatal cases (83%) also had bacteremia. Conversely of the cases that recovered, with pneumothorax 17 per cent only had bacteremia and of the controls 20 per cent had positive cultures.

In the non-toxic group, 2 were treated with pneumothorax. One was positive and died; the other was negative and recovered. Of the 12 non-toxic controls one was positive and 11 negative; all recovered (Table VI).

Let us now study the tables of Lieberman and Leopold. We find that in their Table 2, concerning the dogs treated with pneumothorax that recovered, 40 per cent had positive cultures whereas of the untreated dogs that died, 70 per cent had positive cultures. Furthermore 12 of these animals were so toxic that they died between 24 and 72 hours; at the most, 24 to 48 hours after pneumothorax could have been induced (Table VII).

As for the theoretical considerations of the possible influence of pneumothorax upon the course of pneumonia, I confess that outside of the possible relief of pain, due to the separation of the two favorable pleural layers, I am not ready to accept the opinion of Behrend and Cowper and Blake. Before entering any discussion upon this subject we must first arrive at an understanding of the pathogenesis of the disease. Blake does not admit the obstructive nature of lobar pneumonia. However, he offers no explanation of the decrease in size of the pneumonic lung and of the elevation of the

diaphragm, notwithstanding the considerable increase of the weight of the diseased lung. Neither does he offer any explanation of the crisis occurring between the 5th and 11th days, independently of the presence or absence of antibodies, or, of the abortive cases, or, of the unresolved pneumonias. I think that Birnbaum and myself have presented experimental and clinical evidence in favor of the obstructive theory of lobar pneumonia which so far has been corroborated by all investigators who have repeated our work and has been refuted by none. If this conception be true, it is not immobilization of the lung that is needed, but drainage, liberation of the obstructed bronchi, and ventilation of the lung. In the examples used by Behrend and Cowper of infectious arthritis, cellulitis and pleurisy in which, they say, rest is necessary, we shall answer that rest may be useful, but the most important factor for the treatment is drainage and the more promptly and skilfully it is instituted the better for the patient. On the other hand I do not think that any kind of comparison can be established between pneumonia and tuberculosis as attempted by the same authors. The pathogenesis of these two diseases and the biology of their respective pathogenic micro-organisms is quite different. If we desired to compare the action of pneumothorax on pneumonia with its action on another suppuration of the lung it would be more reasonable to compare it with abscess of the lung, putrid or not, or to bronchiectasis. In these diseases also, pneumothorax was advised with no less enthusiasm than it is in pneumonia today. We know what the results of the use of this treatment have been.

In conclusion, I would say without any intention of being dogmatic, that I do not believe that the fundamentals of pathologic physiology of the pneumonic lung, or the experimental findings are in favor of treatment of lobar pneumonia by artificial pneumothorax. Therefore I was greatly interested in hearing that Dr. Bullowa, in his thorough clinical investigation of this question, had arrived at the same conclusion.

PERFORMING SURGICAL MIRACLES

Transplantation of a toe to replace a forefinger lost in an accident was demonstrated by Prof. M. I. Kuslik of the Vreden Traumatological Institute at the meeting of the Leningrad Surgeons' Society, according to the *Science News Letter*. The patient can

now bend his forefinger, which used to be the second toe on his foot, at will. Prof. Kuslik followed the transplantation technic devised by Prof. Vreden which has been successfully used in three other cases that are similar.

THE TREATMENT OF OCULAR AFFECTIONS WITH GOLD SODIUM THIOSULPHATE

IVAN J KOENIG, M D, *Buffalo*

There are many ocular conditions in which the etiological factor is not demonstrable. The cause of such cases is usually catalogued as one of unknown origin. When thorough investigations do not reveal anything specific, our therapeutic attack must be empiric and with all known measures. The better known methods are usually first thought of and the uncommon measures are frequently overlooked. Several such cases came to our attention and as often develops, we became desperate in our therapeutic endeavors.

It was during the course of treatment in several chronic ocular inflammatory conditions that we began using gold sodium thiosulphate intravenously.

The chronic type of uveitis is particularly responsive to gold therapy. Not infrequently these cases, because of their non responsiveness to therapy, are diagnosed as tubercular.

The diagnosis of ocular tuberculosis in many conditions is concluded only from observation and is not proven by time-honored laboratory methods. In cases of this type one clinician may advise non-specific foreign protein and another may recommend tuberculin therapy and often time neither treatment brings the desired response. It is for this type of case that intravenous administration of gold sodium thiosulphate is advocated.

We began intravenous gold therapy after observing a young Filipino who entered the Buffalo City Hospital June 9, 1932 with a history of a gradual blurring of vision in each eye. Examination of the eyes revealed no abnormality externally. Corneae were clear. The slit lamp showed clear anterior chambers and clear lenses. The vitreous presented a dense haze of flocculent opacities. A very faint fundus reflex could be seen but no fundus detail observed.

Physical examination was essentially negative except for a positive reaction to 1 minum of a 1-10,000 O T intradermal

injection. A focal reaction could not be seen. The visual acuity was 6/60 in each eye.

The treatment consisted of dionin and sub conjunctival injections of saline solution and KI to the point of tolerance along with a vigorous course of purgatives. Two months later there was no improvement in vision and the vitreous appeared the same.

About three months later on August 23, he was given 10 mgm of gold sodium thiosulphate intravenously with subsequent weekly injections of increasing doses. After two weeks there was a subjective improvement in vision. Injections were continued weekly with increasing doses up to 100 mgm. We gave fifteen injections to a course with a month of rest, and repeated them as long as there was improvement in the visual acuity. On August 1, 1933, a year later, the visual acuity had increased to 6/9 and corrected to 6/6. At this time the fundus had cleared and we were able to observe extensive areas of retino chorioidal atrophy at the extreme periphery.

The results of this therapy were so startling in this instance that we continued to choose cases with dense vitreous opacities causing a decrease in the visual acuity, and after these cases would not respond to other therapy.

The use of gold as a therapeutic agent is an old one. One of the first references to it dates back to the beginning of the eleventh century when Avicenna recommended it as a blood purifier. In the early sixteenth century, Paracelsus used gold and mercury in a solution and called it the "Elixir of Life" which was supposed to cure all diseases. At various times it has been brought into prominence as a valuable agent against the tubercle bacillus and then discarded again. Robert Koch in 1890 announced that gold cyanide had a high inhibitory action on the tubercle bacillus. In dilutions of

*Read at the Annual Meeting of the Medical Society of the State of New York,
Albany, May 14, 1935*

1-2,000,000 the growth of this organism was inhibited on artificial media but had no influence in the animal body. Bruck and Glueck in 1913 reported good results in the treatment of lupus erythematosus and it is now used extensively by dermatologists for that condition. Mollgaard of Denmark in 1924 attracted great attention by reviving the use of gold as a cure for tuberculosis. Much discussion arose and many articles have appeared in foreign literature since that time claiming both good and poor results. The preparation used by Mollgaard was gold sodium thiosulphate, also known as sanocrysin. Authorities using the preparation reported observing marked reactions after giving large doses which caused complications for the patient. These reactions consisted of gastrointestinal upsets, stomatitis, dermatitis, renal disturbances, and at times jaundice. Mollgaard explained them as a liberation of toxin from destroyed tubercle bacilli which would be followed by improvement in the patient's condition. Others claimed them due to a heavy metal reaction to which some patients are particularly sensitive. This latter seems more probable because the symptoms vanish with the discontinuance of treatment.

The use of gold in ocular conditions, according to literature, began in Europe. Abramowicz¹ in 1927 published results of experiments with gold sodium thiosulphate, using the solution by a method of electrolysis. In seven experiments he was able to introduce sanocrysin into the eye electrolytically, and the presence of gold was noted in the anterior chamber.

Sander-Larsen of Copenhagen in 1928³ reported treating seventy cases of iridocyclitis intravenously with sanocrysin and other gold preparations. Most of these cases were tubercular. Gold was used after the tuberculin treatment had reached its height with a focal reaction, and good results were reported in both the local and general condition of the patients.

Stoewer⁴ of Berlin in 1928, reported treating tubercular cases with gold (Krysolgan) in cases that did not respond to tuberculin. He reports that absorption of exudative processes was rapid after use of gold. C. Winkler-Prins, Jr.^{5, 6} in 1928 reported a study of leukomatous corneae resulting from tubercular infiltrations

which were treated with sanocrysin intravenously after which deposits of gold were found histologically in the cornea. They were found just outside the walls of the blood vessels and these deposits were always intracellular.

In 1930 Hoffman⁷ divulged beneficial results in treating eye complications in leprosy with Cryolgan, another gold preparation.

Benedict and Goeckerman⁹ in one of the few references in American literature gave a very comprehensive routine for the treatment of uveitis. They advocated the use of gold sodium thiosulphate in cases where the acute signs had subsided or in the chronic type of case not necessarily tubercular. Six cases were reported, and all showed evidence of improvement.

C. M. Berro and P. Cantonnet Blanch⁸ in 1932 reported a case of phlyctenular keratitis which cleared up with intravenous gold therapy after resisting other forms of treatment.

Another use of gold sodium thiosulphate is reported by E. Stastnik.¹⁰ He gave intravenous gold along with other therapy in cases of optic atrophy, five cases of tabetic, two of post neuritis and one case of cerebral lues. Definite improvement was noted in the visual acuity and also color perception.

In considering the indications of gold therapy in ocular conditions it would seem that value may be found in its use when given in the chronic type of case that may or may not simulate a tubercular process.

Another of our early cases is that of a white female aged 60, who on August 22, 1932, had an intracapsular extraction of a mature cortical cataract of the left eye. Her convalescence was uneventful except for a low grade iritis which was easily controlled and the patient was discharged from the hospital on the tenth day.

On October 6, 1932, refraction was done which with a +12.50 +200 ax 170 gave 6/9. Lenses were given for constant wear. On November 1, 1932 the patient returned complaining of blurred vision, it being 6/15 with correction. Examination revealed cellular deposits on the posterior surface of the cornea with a cloudy anterior chamber. Foreign protein was given intermittently for six weeks in addi-

tion to potassium iodide and local treatments of atropin sulphate and diosmin with no improvement objectively or subjectively. Physical examination revealed a hypertension with vascular changes, a slight secondary anemia, also some emaciation, a trace of albumin in the urine with an essentially normal blood chemistry. Mantoux reaction (1-10,000 mg O T was 2+).

This patient was started upon gold therapy with an initial dose of 10 mgm on December 30, 1932. The treatment was continued for 8 doses with increasing amounts each week. The development of a slight dermatitis was the reason for withdrawing intravenous treatment. However, her visual acuity had improved 6/9 again with the same correction by this time.

In addition to the improvement in vision, there was a gain of ten pounds in weight and all through her course there was a general feeling of well being which the woman had not had in months.

Other cases selected for this treatment were cases of dense vitreous haze, some being exudative and others hemorrhagic. In all cases intravenous gold was used only after other forms of treatment and the elimination of foci of infection failed to bring about any improvement. Several cases of severe iridocyclitis were treated after the acute symptoms had subsided and a vitreous haze remained causing a diminution in visual acuity. These vitreous exudates seemed to absorb more readily after gold was used.

An example of a case of this type was R. H., male, aged 43, who had had a supposed sympathetic ophthalmia of the left eye since July, 1922, following an injury to the right eye. Since that time he had been under intermittent hospital care with attacks of severe iridocyclitis about once a year. The right eye had been enucleated shortly after the accident following an iridectomy by the late Lee Masten Francis, who made the diagnosis of sympathetic ophthalmia which was corroborated clinically by many other ophthalmologists. This patient has been under my observation since 1923. The failure of the right eye to respond to iridectomy made it inadvisable to attempt a similar procedure on the remaining eye.

The periods of hospitalization varied

anywhere from six to eight weeks. In addition to the usual local treatments he was given various non-specific foreign proteins including milk, diphtheria antitoxin in small doses as well as the larger doses advocated by Verhoeff, autogenous vaccines from teeth, and typhoid vaccine. The latter seemed more efficient in relieving the acute symptoms than the others which had been given in previous years. There had been little change in the appearance of the eye during the attacks, all of which seemed alike. The findings were typical of a very severe iridocyclitis. The endothelial surface showed large grayish white deposits, a turbid aqueous, extensive posterior synechia, and exudation into the vitreous. The uncorrected visual acuity was always 6/6 after each attack.

The last attack began January 17, 1933. After intravenous typhoid therapy the acute symptoms subsided more rapidly but the media remained hazy longer than usual. The visual acuity remained 6/15 for a period of three months. With the visual acuity apparently stationary gold sodium thiosulphate was given. After ten doses, the maximum being 100 mgm, his visual acuity improved to 6/9 which it held until another attack of iridocyclitis recently, which was not as severe nor as long standing as any of the other attacks. Physical examinations over a period of years revealed several positive findings, such as two infected teeth in 1927 and one anti-complimentary Wasserman in 1928, the others all having been negative. Through careful search no definite etiological factor had been demonstrated. In this case we felt that absorption of exudate from the vitreous was hastened by administration of gold intravenously.

Another case, F. W., female, aged 49, came to me for refraction in 1926, the corrected visual acuity being 6/5 in each eye. The external and fundus examination was negative except for slight evidence of early vascular sclerosis. On July 1, 1929, she again consulted me complaining of spots before her eyes. The corrected vision was 6/5 in each eye.

External examination was negative including a slit lamp study of the anterior segment. The fundi revealed string-like and fine opacities of the vitreous with no

lesions of retina or choroid. She was referred to her physician who reported a myocarditis with some vascular changes. Wasserman and Mantoux tests were both negative, and the blood chemistry was within normal limits.

The patient went to Europe during the summer and returned in September, 1929, with continued symptoms of photopsia. The corrected visual acuity was 6/6 in each eye. At this time she was using dionin, while sodium iodide intravenously was being started.

During the next year iodides, dionin and sub-conjunctival injections of saline solution were given at various intervals. The visual acuity became steadily worse. The opacities of the vitreous became more numerous and string-like.

On October 20, 1932, the visual acuity of the right eye was 6/15, of the left eye 6/12 and this would not improve with other lenses. At this time the opacities were quite flocculent and more massive than before.

Gold sodium thiosulphate was started intravenously. The initial dose of 10 mgm. was given and gradually increased to 100 mgm. Her visual acuity began to improve after the tenth injection. On December 28, 1932, the visual acuity with the same correction had improved to 6/6 in each eye, and the opacities of the vitreous had decreased both in size and number. The patient also stated her general condition improved after beginning gold therapy. The visual acuity, on her last visit, February 5, 1935, was 6/6 in each eye with the same correction.

A corneal lesion that showed response to gold therapy was found in P. S., white, male, aged 49, with a history of very poor vision in the right eye for years and the left eye for months. He came to the Buffalo General Hospital dispensary service on April 7, 1932. The right eye was quiet, showing a superficial corneal scar with dense vitreous opacities through which no fundus detail could be seen. The left eye presented many deep infiltrates of the cornea. On April 4, 1933, after exhausting all other therapeutic measures, we began the use of gold sodium thiosulphate intravenously. At this time the right eye was similar to the previous examination, but the left eye revealed dense surface scarring. In

the deeper corneal layers near the apex, there was a large white infiltrate about 3 mm broad which was rather sharply defined. The vascularization was quite marked. The eye continued to be irritable in spite of atropin and vaccine treatment which had been given. The diagnosis in this case was uncertain. I hesitate to call it more than a chronic keratitis. The cornea on this case began to clear of infiltrates after receiving five injections of gold, and the acute symptoms began to subside. A 1 per cent solution of atropin sulphate was the only other local treatment that had been continued. On May 23, 1933, the local treatment was discontinued and the eye was quiet. The infiltrates had absorbed, and only dense scarring on the cornea remained. The right fundus, too, was clearer. The vitreous haze had thinned so that we could observe areas of choroidal atrophy which prevented any useful vision on the right side.

On June 20, 1933 the eye remained quiet for a month without local treatment. This patient had fourteen intravenous injections of gold. In this case the eye remained quiet for several months. At a later date a recurrence developed, but I was unable to follow the case further.

We have tried gold therapy on many chronic ocular conditions which failed to respond to other routine treatment. The cases we find particularly responsive to therapy are those where exudation from the uveal tract has caused a hazy vitreous.

In the vitreous we have many different types of opacities. The etiology of such opacities, especially in people past middle life, is not always demonstrable. Some of them are hemorrhagic and others are exudative processes. Some other causes of such opacities are inflammation of the retina, and uveal tract, trauma producing hemorrhages from the choroid or ciliary region, and exhausting diseases, such as anemia, syphilis, tuberculosis, focal infections, constipation, congestion of the liver, mental disorders, vascular sclerosis and others.

One or more of these diseases, along with a hazy vitreous, may exist in an individual, and the treatment of these conditions many times fails to improve the visual acuity. It is not every case that will respond to the intravenous use of gold, but in the case where other thera-

peutic endeavor has failed, this treatment is worth considering

The complications noted in its administration were few. The most common was a stomatitis. The development of a dermatitis has been noted, and, in one instance, a gastrointestinal upset could be attributed to it. In a series of upward of thirty cases, complications were had in only five, all of which were eliminated by withdrawing the drug. Liver pathology is one that should be watched for, but in our cases it had not been observed.

The routine of administration we have been following recently is to start the individual with a dose of 10 mgm and to increase this to 25 mgm for a total of six weekly doses. The small initial dose is given to detect any sensitivity to the drug. At the end of the sixth treatment, the dose is increased to 50 mgm until a total of 15 doses have been given. Due to the fact that gold is excreted slowly, it is felt that the weekly injections are sufficient for metallic action. Also sensitivity can be

observed more readily by small and infrequent doses.

A month's rest is given after which the 50 mgm dose is again administered and if necessary continued for fifteen doses. If no improvement is noted in this time, the probability is that none will result.

It is not claimed that there is any specific action in gold for ocular tuberculosis or for any chronic uveitis, and it should not be used in place of other well-recognized procedures but merely as an adjuvant with other routine treatment.

The cases cited are mostly of questionable etiology but they have all shown improvement in the appearance of the existing pathology during the course of gold therapy. They are not presented to state conclusively that the improvement can be entirely credited to the use of gold sodium thiosulphate but are merely given to show the type of case which can benefit when gold is added to the more routine treatment.

WHY AN AUXILIARY?

The campaign now well under way to form auxiliaries to the county and state medical societies gives point to the question raised in the *Wisconsin Medical Journal*, "Why an Auxiliary?" We might as well ask, "Why a Wife?" says the writer, who dips his pen in effervescent ink and gives us this:

Medical organization went on for nearly a century in a state of single blessedness. Like an old bachelor it never seemed to realize that it was doing many odd jobs which could be done by a helpmate and that its standing in the community was being sorely neglected. Then one spring morning some ten years ago came a comely lady, who announced herself as Mrs. Auxiliary, rolled up her sleeves, nudged Mr. Medicine

in the side, and said "shove over—I'm going to pitch in help get your house in order, and I'm going to be your partner."

The old fellow, unaccustomed to team work, grumbled and still sputters at times, but down in his heart realizes how efficient she has been. During the years she has grown and developed into a buxom housewife on whom he has learned to depend more and more. She has been helpful in more ways than he realizes and she can do more and more for him as time goes on and he learns more to rely on her. Her main job is to improve his standing in the community. He has been a hermit and has covered up his sterling qualities and his good deeds. He has had few contacts with others and she can do much in bringing about a better appreciation of his work and of his worth.

TRAUMA AND TUBERCULOSIS

EDGAR MAYER, M.D., *New York City*

One year after the excision of a tuberculous epididymis, a man, aged 42, showed evidence of recurrence in the remaining epididymis and prostate. Following three months of conservative therapy, the patient felt well enough to go surf-board riding. A severe fall during this exercise was followed in three weeks by a widespread miliary tuberculosis and death. The family collected double indemnity insurance on the basis of traumatic death.

A housewife, aged 38, entered the accident ward of a municipal hospital, unconscious, from a probable fractured skull following an automobile accident. Consciousness was soon recovered followed by a three week's period of fever ranging between 102 and 104° F., tachycardia, sweats and dyspnea. Roentgenograms of the lungs, taken two weeks previous to admission to the hospital in the course of a routine physical examination, had shown no tuberculosis. Subsequent x-rays taken seventeen days after the accident showed a miliary tuberculosis of the lungs. Autopsy records revealed, aside from the miliary tuberculosis, a large caseous tuberculoma in the left frontal lobe, and no fracture of the skull. This family likewise collected double indemnity insurance on the basis of a traumatic death.

A superintendent of an apartment house, aged 46, fell four floors down an elevator shaft and suffered a severe injury to the chest, fracturing the left 6th, 7th and 8th ribs. This was followed by frequent pulmonary hemorrhages over a period of one year. The patient had had for three years, a slight cough and rare mucopurulent expectoration. Examination of the sputum subsequent to the injury showed on only one occasion two acid-fast rods, and although x-rays of the chest were negative, still tuberculosis was diagnosed. The patient had then been allowed compensation for a traumatic tuberculosis. When, at the end of two years, lipiodol

studies were made, extensive bilateral cylindrical bronchiectasis was revealed and the diagnosis of tuberculosis was then ruled out. Subsequently, a relationship between trauma and the aggravation of an old bronchiectasis was granted in the claims made.

Problems like the foregoing, regularly involving the question of relationship between injuries and pulmonary complaints, has prompted the following study.

Causal connection between trauma and tuberculosis has been assumed from earliest times. Instances of pulmonary tuberculosis following blows to the chest have been described in records from antiquity. Herodotus relates that Xerxes, the Persian king, died of phthisis developing after a hemoptysis as a result of a fall from his horse. Similar observations have been reported by Portal and Laennec and many others since. In our own day literature continues to present such reports from time to time, although on the whole, with advancing knowledge of the pathogenesis of pulmonary tuberculosis, such cases are being looked upon more critically. To be sure, the number of cases in which traumatic origin of phthisis is claimed to have been established is actually declining rather than increasing.

There are statistical reports regarding the incidence of tuberculosis following traumatic injury, but these refer to analyses of material and of conditions as they existed nearly a generation ago. In the meanwhile, our conception of the pathogenesis of pulmonary tuberculosis has undergone such remarkable changes, even in the last decade, that new statistical analyses will be required to estimate the incidence of traumatic tuberculosis.

Trauma and Infection in General

The relationship between trauma and tuberculosis is essentially comparable with that which exists between injury and other infections. It is now generally ac-

From New York Hospital, the Department of Medicine of the Cornell University Medical College. Presented in abstract at the Clinical Session of the American Society of Thoracic Surgeons, New York City, June 1935

cepted that the principle upon which this connection is based is expressed in the so-called law of Schultze, namely, in the presence of trauma, microbic organisms circulating in the blood stream will tend to localize at the site of injury which constitutes a point of least resistance. Recent experiments of Gmelin¹ have shown that an injured part of the body will almost always become a favorable site for metastasis in case of bacteriemia. This has also been borne out by clinical experience. Abscesses have been observed to grow at the site of a needle puncture in patients with bacteriemia. Even the minimal injury of a needle puncture suffices, in the presence of generalized infection, to serve as a point of lowered resistance. Studies of Ricker² demonstrated that in a traumatized area there is present a so-called peristatic hyperemia, implying obstruction to capillary blood flow, and congestive edema in the surrounding tissue. This peristatic hyperemia is identical with the pathological phenomenon observed in the first phase of infection. Organisms circulating in the blood stream will be readily taken up by soil thus prepared for their growth and activity. The congestion in traumatized tissue must not be confused with Bier's hyperemia, in which there is increase of blood quantity without interference with rate of blood flow through the part, so that elements for healing are conveyed to, while toxic or decomposition products are transported away from the injured area. In the peristatic congestion of Ricker, however, there is merely a static increased quantity of blood in an injured part without an adequate rate of flow.

Aside from a local action, trauma predisposes to infection through its general effect upon the body. Thus, when subjected to mechanical trauma or any sort of shock, the body suffers a decrease of vitality involving also diminution in defense powers against infection. Moreover, mechanical damage of some degree is associated with some extravasation as well as destruction of cells with accompanying physical and chemical changes, of which one manifestation is the aseptic absorption fever. The non-mechanical effect of trauma is due primarily to shock, a state profoundly affecting the neurovegetative functions of the body, which are so im-

portant in the maintenance of the immunobiologic balance.

Trauma and Tuberculous Infection

The causal connection between trauma and tuberculosis is never quite as obvious as is that between trauma and other infections. This is due to the high incidence of spontaneous tuberculosis among the general population, the frequency of latent lesions, and the characteristic delayed and chronic mode of development of tuberculosis.

In the relationship of trauma and tuberculosis, the following possibilities are to be distinguished: (1) Traumatic inoculation tuberculosis, i.e., introduction of tuberculous infection into the body by trauma. (2) Traumatic reactivation of tuberculosis, i.e., the opening of old perfectly healed lesion by trauma. (3) Traumatic exacerbation of tuberculosis, namely, unmasking a latent though active lesion by trauma. (4) Traumatic aggravation of tuberculosis, i.e., enhancement of a known active tuberculosis process by trauma.

These possibilities must be considered separately.

1 *Inoculation tuberculosis*. While commonly pyogenic bacteria are introduced into the body directly with and at the site of trauma, this is a rather uncommon occurrence with tubercle bacilli. Under exceptional conditions, trauma may introduce tubercle bacilli into the body. A considerable number of cases have been reported of tuberculous infection introduced in the course of circumcision when it was unhygienically carried out by phthysical mohels. A recent exhaustive report of Finkelstein³ is of interest in this connection, as it shows this to be of more frequent occurrence than is generally realized. Cases have also been recorded of infants infected with tuberculosis through eczematous skin lesions by phthysical attendants. A very unusual case was recently reported by Incze⁴ of a primary tuberculous infection occurring at the site of an esophageal stricture in a child who had accidentally swallowed lye and was boughed by a tuberculous attendant. Traumatic entrance of bacilli has been observed not uncommonly in lesions acquired with accidental injury by prosectors at autopsies and by veterinary sur-

geons and butchers who have inoculated themselves while cutting up tuberculous cattle. Laennec himself traced his pulmonary tuberculosis to a finger infection previously obtained in the course of an autopsy. Yet such inoculation tuberculosis is a curiosity and of little practical significance.

2. *Traumatic reactivation of tuberculosis* is of much greater practical significance. Trauma may injure a part of the body where a tuberculous lesion exists, directly reactivate it and cause it to extend locally, and possibly to other parts of the body, through the blood stream. Although the contention of Lowenstein⁵ as regards the high incidence of bacilleamia has not been substantiated, we know from the recent studies of Wilson⁶ that tuberculosis bacilleamia does occur more frequently than is generally believed.

Traumatic reactivated tuberculosis is perhaps the most frequent traumatic form met with in practice. With the prevalence of tuberculous infection in individuals living in a civilized community, the possibility of injury reactivating a healed lesion can hardly be excluded in any cases where the development of clinical tuberculosis following trauma has been demonstrated.

3. *Traumatic exacerbation of tuberculosis* is next in significance. Under certain circumstances a tuberculous lesion may exist and even extend without producing symptoms, the patient remaining unaware of the process for a long period or forever. Trauma occurring during this period may unmask such latent yet active lesions, and under such conditions, may increase the activity of the focus so as to render the patient conscious of it through the production of manifest clinical symptoms.

Here, trauma merely precipitated the clinical recognition of a tuberculous process which would perhaps have revealed itself later spontaneously. Still, but for the trauma, the smoldering lesion might eventually have come to complete healing without ever leading to clinical disease. Therefore, injury must here be considered responsible for the tuberculous process having changed from a latent to a clinically manifest disease.

4. *Traumatic aggravation of tuberculosis*. We are dealing here with a manifest tuberculous process which has become demonstrably aggravated in connection

with an intervening injury. In view of the fact that tuberculosis is a periodically relapsing disease, the possibility of a fortuitous coincidence must always be considered when an aggravation follows a trauma. It is obvious, therefore, that the connection between the trauma and the aggravation of the process which followed it, must be established with reasonable certainty.

Forms of Traumatic Tuberculosis

Traumatic tuberculosis is commonly classified into extrapulmonary tuberculosis of traumatic origin and traumatic phthisis localized to the lungs. The former is more of a surgical, the latter an internal medical problem and of greater interest to us here.

With regard to *trauma and extrapulmonary tuberculosis*, it may suffice briefly to point out that the causal relationship is very often quite clear and decisive. The literature abounds in reports of traumatic reactivation of pre-existing tuberculous foci, particularly in bones and the genitourinary tract. According to some authorities, one-fourth of the cases of bone and joint tuberculosis are attributable to trauma. Quite often such reactivation results in fatal generalization in so short a time following trauma and under such circumstances as to exclude any uncertainty with regard to the connection between the trauma and the disease.

The literature also includes a considerable number of reports of instances in which surgical tuberculosis was reactivated by operative interventions, and instances, moreover, in which surgical intervention even led to fatal tuberculous generalization. A recent report of particular interest in this regard is that of Buegeler⁷ who autopsied a woman whose death was a result of curettage of an unsuspected tuberculosis of the uterus. Another very interesting recent report of surgical traumatic tuberculosis is that of Schuller⁸ in which orthopedic intervention upon an unsuspected part led to tuberculous involvement of that part of the body.

Trauma and Pulmonary Tuberculosis (Phthisis)

The relationship between trauma and tuberculous disease is never as clear in

the lungs as it may be in the case of other organs.

The lung is the point of entry for spontaneous tuberculous infection in an overwhelming majority of instances. By recent roentgenological, as well as postmortem evidence, 90 per cent of people in civilized communities are tuberculized by the time they reach adult age. This means that they had not only a primary childhood infection, but also a subsequent reinfection. For the most part, everyone harbors in his lungs not only the primary focus but also a secondary post-primary focus of the Simon or Aschoff-Puhl type. The site of predilection of these reinfection foci is in the upper third of the lung. From pathological evidence it is apparent that even primary foci, no matter how obsolete or calcified they appear on x-ray, are nevertheless accessible to flare-up. Lung scars and calcified nodules may contain viable tubercle bacilli. Pathologic study has also shown that anyone may harbor a reinfection focus which, though inaccessible to clinical or roentgenological demonstration, may yet contain caseous infectious matter. Such a lesion, when exacerbated, may become a source of dissemination, leading to an extensive phthisical process.

The lung furthermore is the first station in the pathway of a lymphohematogenous dissemination. The tendency for tuberculous infection to persist in some part of the lymphatic system of the body is well known. When tubercle bacilli invade the blood stream from any focus in the body, they are filtered out first in the lungs. Any injured part of the lung would therefore obviously be a point of lowered resistance.

Instances of pulmonary phthisis forming at the site of injury, are reported where the circumstances were such that its development could not be otherwise explained than on the basis of the trauma itself. Such instances are exceptional, because traumatic phthisis, like other forms of pulmonary tuberculosis, usually begins and extends from a summit of the lung. In the majority of cases of traumatic phthisis, we are dealing not with the production of a new lesion at the site of injury, but with an extension from pre-existing older lesions.

Here again, trauma may light up an old

healed lesion, unmask a latent lesion, or aggravate a previously mild process in the lung.

The following general types of injuries must be considered as playing a role in the traumatic origin of phthisis: (1) Mechanical injury to the body as a whole. (2) Mechanical injury to the chest and lungs. (3) Thermal trauma (exposure to injurious weather conditions). (4) Chemical trauma (inhalation of injurious gases and fumes).

1. *Phthisis due to general body trauma.* There are well-recognized instances of tuberculosis extending to the lung after a bad fall or a blow to another part of the body harboring a tuberculous lesion. A bone tuberculosis if injured, may cause a complicating pulmonary tuberculosis. The same is true for genitourinary tuberculosis, particularly after injury to the scrotal contents. Clinical observations correlated with postmortem records provide ample illustration of this fact. Extension of tuberculosis from the genitourinary tract to the lungs has occurred in men with prostatic tuberculosis as a result of prolonged and severe bouncing while riding horse or bicycle. Under such conditions the lung would be the first organ invaded by bacilli entering the blood stream.

Tuberculosis may engraft itself upon other conditions, and in individuals debilitated by other diseases. Thus we see "phthisis of the amputated" and of the cachectic and long-confined patient. In the days before insulin, tuberculosis was much more frequent in diabetics than is the case today. Psychopathic individuals have been known to be more liable to tuberculosis, perhaps by reason of debilitating improper nutrition, unhygienic mode of living and similar depressing conditions.

2. *Phthisis due to chest trauma or a lung injury.* The late World War contributed abundantly to our knowledge of the general effects of penetrating injuries of the chest. In the light of this knowledge, it is doubtful whether tuberculous infection can be carried into the lungs by penetrating wounds of the chest. To be sure, such wounds are hardly ever followed by pulmonary tuberculosis. The incidence of post-traumatic pulmonary tuberculosis is estimated at less than two

per cent of cases of chest injuries. Graham⁹ and his associates contend that spread of pulmonary tuberculosis is responsible for the greater part of the mortality occurring in surgical treatment of pulmonary tuberculosis. However, aspiration of infectious matter is blamed for this rather than surgical trauma.

In war injuries it was the general shocking effect of severe trauma to the chest which led to tuberculosis. Shot or stab wounds were found very much less often associated with subsequent appearance of pulmonary tuberculosis than was traumatic concussion of the chest.

Superficial chest injuries, such as are produced by severe blows or the lifting of heavy burdens, may cause a tear in the lung or a *pneumothorax*, though there may be no visible evidence externally. Conversely, external signs of chest injury with or without contusion or fracture of ribs may give no clear idea of the extent of injury to the deeper thoracic structures. *Pleural effusions* of purely serous nature are mostly of tuberculous origin, and it is fair to assume that the occurrence of non-sanguinous pleural effusions, following trauma, indicates reactivation of tuberculous lesions. Trauma of milder character occurs in the everyday course of events without serious effects, yet it is conceivable that even a relatively slight injury may, in a person with quiescent or manifest tuberculosis, sufficiently upset the balance between inflammation and repair or healing. With general resistance depressed, a trauma may overturn the equilibrium of defense forces. Little knowledge is available regarding the nature of resistance to tuberculosis or its related allergy, in the production of tuberculous disease and so, it is not possible to make positive assertions regarding the mechanism involved in the traumatic causation of phthisis.

Hemoptysis is one of the most frequent symptoms resulting from trauma to the chest and presumably represents more or less severe injury to pulmonary tissue. Such lung injury may exist without obvious external effects. The importance of such a lung injury resulting in hemoptysis is often much overestimated, from the standpoint of traumatic phthisis. It is not the immediate hemoptysis from the injured lung but rather the late hemorrhage

from breaking down of the traumatic tuberculous foci that is of practical significance.

3. *The role of thermic trauma.* Exposure to cold may act as a trauma leading to development of pulmonary tuberculosis. Cases are on record where undue exposure to extremes of cold and wet have led to such development. Workers thrown accidentally into icy water, soldiers exposed to cold and wet in the trenches, have subsequently developed manifest phthisis. Chilling is a likely factor in bringing on pleural effusions, probably by reactivating pre-existing latent *sub-pleural tuberculosis*. However, this sequence of events is not accessible to demonstration and there is, of course, no instance on record where this connection could be proven from clinical experience.

There is no conclusive evidence that thermic trauma will bring on tuberculosis; nevertheless, it cannot be entirely excluded as a cause. Chilling may provoke respiratory symptoms resembling the common cold or grippe and these may often be manifestations of early tuberculosis. Lesions produced by such affections may involve lung or tracheo-bronchial lymph nodes containing tuberculous lesions which may thus be reactivated.

4. *The role of chemical trauma.* Chemical injury to pulmonary tissue or damage as a result of inhalation of various gases and fumes are really forms of local trauma. *Chemical trauma* to the lung is a well-recognized demonstrable fact. A more protracted insidious form exists in *silicosis*. Other equally serious and more acute forms of such trauma occur in connection with *irritating gas and vapor* inhalations. While the incidence of tuberculosis following war gas exposures was not very conspicuous, yet more recent evidence on inhalations of industrial fumes indicates that where such exposure is prolonged or severe and concentrated, it may serve to reactivate pre-existing healed lesions.

Medicolegal Aspects

From the medicolegal standpoint, the principle to be emphasized is that each case must be decided on its own merits. The history, clinical findings, x-ray studies, and clinical course must all be considered and evaluated as evidence

bearing upon the special aspects of the case

The guiding criteria, as established through innumerable precedents, are as follows (1) The severity and character of the trauma (2) Its nature (3) The condition of the patient before the accident (4) The age of the patient (5) The time element existing between trauma and onset of disease (6) The continuity of relationship between trauma and its recognized direct and ultimate effect upon the patient

The trauma obviously must be of such severity as to affect untowardly the entire body or injure considerably some part of it. Reliable information regarding the patient's condition preceding the trauma is needed to determine the probable effect. It is logical to assume that in a person who had been engaged in heavy manual labor up to the time of trauma, manifest tuberculosis arising in direct relationship with such injury is more likely attributable to that injury than in the case of another individual of sedentary occupation. It is more likely for a pre-existing pulmonary lesion to remain latent in a person whose occupation does not expose him to physical hardships.

Age of the patient is next in importance from a medicolegal standpoint. Tuberculosis following trauma is more likely related to injury in a young robust individual with great natural resistance, than in one past middle age whose natural resistance is more likely to spontaneously diminish with advancing age. Also, it is conceivable that in an older person accidental injury may prove the last straw in accelerating the awakening of a lesion which was already on the way to spontaneous reopening, yet under such circumstances, it is rarely possible to fix the exact role of trauma in its production.

The *time element* between trauma and onset of disease must be reasonably established. Where one has apparently enjoyed good health up to the time of the chest injury and then within a reasonable period following this, symptoms of pulmonary tuberculosis become manifest, the assumption of a direct relationship between the trauma and tuberculosis is justified. Inasmuch as tuberculosis is a slowly developing disease it is not feasible to set a *time limit*. To postulate a definite time limit in

days or weeks is in error, as it may take months for a tuberculosis to become manifest. Neither, however, is it possible to leave the time element altogether open as this would provide too broad a loophole for claims of traumatic disease following years later. Therefore, a conventional time limit must be set, and if tuberculosis is due to trauma, it seems fair to assume that diagnosis should be possible within six months after an accident. However, outspoken symptoms such as cough, expectoration and hemoptysis should manifest themselves much earlier, in fact, within a month, and there should be a continuous time link of clinical symptoms between the trauma and the first demonstrable lesion. Where it is claimed that the tuberculosis arose immediately after trauma, the relationship to the injury is very doubtful, in such cases there is rather strong evidence that pre-existing active tuberculosis was aggravated by the trauma. Traumatic hemoptysis is no evidence of traumatic phthisis. Where hemoptysis immediately follows trauma in a patient with healed tuberculosis, it does not necessarily indicate even reactivation of the old lesions, but may signify mechanical opening of a vessel from pull of adhesions or a scar. Hemoptyses may occur from trivial causes and are frequently observed in cases even with healed tuberculosis, without leading to activation or progression of the disease. Some may even be due to an old bronchiectasis or a fibrotic area. However, if the trauma was severe and followed with a reopening of a healed lesion within a "reasonable" period of time, the connection may well be substantiated, if the above mentioned manifest symptoms of tuberculous disease followed the injury in a more or less continuous relationship and linkage. It must be shown that the patient was "never well" since the occurrence of the trauma, that a quiescent lesion was transformed into chronic disability, or that recovery was considerably retarded.

Conclusions

From the foregoing, the following conclusions may be reached:

1 Under very exceptional conditions, trauma may undoubtedly introduce tuberculous infection into the body

2. As a rule trauma either reopens a healed lesion, unmasks a latent lesion, or aggravates a manifest lesion.

3. Pulmonary tuberculosis may arise following mechanical, physical or chemical lung injuries.

4. Pulmonary tuberculosis far more often follows general violent trauma applied to the body or chest, than penetrating injuries to the lung.

5. The lesions of phthisis may exceptionally be found at the site of chest injury, but far more often, they manifest

themselves like those of phthisis in general, in the upper portions of the lung. This indicates that one is dealing with an exacerbation or reactivation of pre-existing apical lesions.

6. The medicolegal evaluation of the individual case depends upon consideration of: (a) the nature and severity of the trauma; (b) the age and condition of the patient before the trauma; (c) the time element and indisputable linkage of the symptoms and first appearance of the lesions, with their traumatic origin.

DR. CHARLES NORRIS, "SUPERSLEUTH"

That is the term applied by the New York *Sun* to Dr. Norris, who died on September 11, and who was for seventeen years Chief Medical Examiner of New York City, and gained international fame for his well-nigh uncanny solutions of mysterious deaths. "In his investigations of sensational murder cases he became to the police almost a supersleuth and to the public almost a legendary figure in the life of the metropolis," says the *Sun*. The *Herald-Tribune* recalls that through one of the most violent eras in the long story of this city, it was the job of Dr. Charles Norris to ring down the curtain on thousands of tragedies, high and low, which ended in death. Homicide and suicide cases, drownings and fatal automobile accidents, all these passed in procession under the keen eyes of this skeptic, who was one of America's leading pathologists, a sound student of human nature and a real character among New York's undistinguished millions. He liked his job and did it well, finding truth at the bottom of some of the city's most celebrated mysteries.

He was immune to influence, the pull of politics, the prestige of high places. He was a man of learning, impeccable integrity, Rabelaisian humor and wide understanding. He called a spade a spade, whoever placed

it on the table. If a man committed suicide and his family wanted it listed as a natural death, Dr. Norris put it down as a suicide—in black and white for all the world to see. He was equally quick to scotch schemes to turn suicides into "murders" to assure double indemnity from insurance companies. Sometimes—as in the celebrated Elwell case—he had to fight hard to convince the other investigating authorities that what they were willing to accept as a suicide had really been a murder.

Again there were times when he wiped out the disgrace of what had seemed a homicide or suicide by detecting that a person had really died of pneumonia. His morgue, to which were brought the victims of stabbings, persons who had inhaled cooking gas, or hanged themselves, or jumped from windows, he called "the Country Club." There, too, were brought those who had drowned, those who fell in gang battles, men and women and children who perished in fires, and all those whose deaths occurred under suspicious circumstances. It required the canny endowments of a highly competent detective, a working knowledge of ballistics, and many other talents, along with the observation and skill of a pathologist, to get at the cause of some of the tragedies.

COMMUNITY HEALTH EDUCATION

G D FORBES, M D , *Kendall*

The subject of community health education covers so vast a field and has so many angles of approach with such a variety of technic that it is absurd to attempt to cover it in any short paper. However, it is fitting to ask anyone to tell something of what he has been able to find out about it in a short paper. In evidence of this I once asked Bishop Hanna, who is now Catholic bishop of the San Francisco diocese, how long a preacher should preach. His reply was "My son, I have known many brilliant men and I have never known a one who could not tell everything he knew in twenty minutes." It is evident that this paper should take something less than twenty minutes.

During the past years we have accumulated a vast amount of information about public health. As technicians in public health we need to learn much more. Unfortunately the non-technical public is bombarded with syndicated articles in the press that contain an amount of information that would have done credit to a course in medicine not so many years ago. Certainly it is not necessary, and it seems hardly desirable, that the man on the street be an expert in matters of health. However, it is quite necessary that he have a working knowledge of certain fundamental principles that he needs to apply in his daily activities of living with himself and in contact with his neighbors. When you come to think about it there are only a few things that he needs to know about any one subject but there are a lot of subjects about which he needs to know those few things. Besides having a working knowledge of the fundamentals it is every bit as important that he be able to recognize the fallacies of that brand of pure hokum that is shouted at him from every loudspeaker in the land. Of these needful fundamentals about health and disease consider only a few and at once we begin to realize the problem facing us. Everyone should know

how diphtheria can be prevented, what to do in case of a bite by a strange dog, the infectiousness of tuberculosis, why everyone should be vaccinated, how diseases like whooping cough and measles are transmitted. Every parent needs to know why the almost inevitable attack of whooping cough and measles should be postponed beyond the high fatality ages of these diseases. Every prospective parent needs to know why the pregnant woman should have a blood Wassermann. Every country dweller needs to know how to arrange a safe water supply and how to dispose of sewage. People in general need to know of the growing menace of syphilis and that it can be controlled. These are only a few examples but from them it is very plain that the man on the street needs to know something about a great many things. It follows that unless the instruction given him is limited to fundamentals he is going to have too much to remember. If he tries to remember too much he will become confused and his blunders may easily be tragic, or he may react by becoming disgusted and forgetting the whole thing. Neither of these results are useful to him. Neither is what we want. The answer is to stick to first principles and leave the details to the experts. It is no benefit to a dairy farmer to know the bone changes that occur in von Bergman's syndrome. It is quite necessary that he know that the germs of lockjaw are commonly found in the stables where he works. Health instructions for the layman need to be simple and it needs to apply to his living and working conditions if we are to get his attention. How to get this information to him is a tough problem and we have to resort to several methods to reach him.

Of all the various means of educating people in health the personal teaching of the physician is still the most important, especially in country communities. How important it is to continue to be will depend upon the efforts of the profession.

*Read at the Annual Meeting of the Medical Society of the State of New York,
Albany, May 14, 1935*

to make it important. There has been much criticism of the old country doctor type. He was too garrulous. He told everything he knew to every patient he saw. There is some truth in this. There is also something to be said against the new type of impersonal, ultrascientific practitioner, who thinks only of cases and seldom of people. He does not waste much time teaching people how to keep well. It may be that in the future this will be the right attitude. When health activities are better organized teaching may be better done by those trained to teach. But at present the practice of medicine is something more than the exchange of a prescription for a fee. The glory of medicine is in the services it has rendered humanity for which it has not been paid. Its almanac of nobility lists those who loved humanity more than they loved themselves. A Grenfell in Labrador. A Noguchi in Africa. Whether you are one who glories in the efficiency of our great medical centers or one who, with all the humility of an Ambroise Paré, is content to say: "I dressed his wounds; God healed him," I submit this proposition to you. When we have brought the patient through his illness and have set his feet on the road to health we have done but half our duty. It is our further duty to sit down by his bed and explain to him how his illness came about and to tell him, if it is possible to do so, how he may so order his life that it will never happen again. When physical disaster threatens and when sickness comes the teaching of the physician is treasured. It is our chance to teach and at the same time to pay the moral debt we owe our patients.

In all our present health educational work there is one great weakness. All our teaching, all our publicity reaches the man who needs it least and fails to reach the man who needs it most. How to bring health education to the back-road farmer who doesn't own a radio, doesn't read a newspaper, and has not read a book for no one knows how many years is a matter about which I am not offering too much advice. Rather, I am asking for it. In addition to the efforts of the local doctor it seems to me that there are two factors operating to solve this problem. The first is the school. When you educate

a child you, in a measure, educate his parents. If there is practical health education in the schools we can reasonably expect that the present generation of school children will grow up having better health habits than our generation has. We may also expect that a certain amount of this information will filter through to other members of that pupil's family. Just how much effect this is going to have on the health habits of the adults is not easy to estimate but at least they will be modified for the better. As a result of this teaching we can hope that those things that we induce the present generation to do with difficulty the coming generation will do as a matter of habit.

The second factor in reaching the back-road farmer is the public health nurse. However, the nurse needs to keep this in mind. These inarticulate farmers are not stupid. They have all the native intelligence of the race but they are embarrassed. They are skeptical of new ideas. The very isolation that protects them from the epidemic diseases that attack the dweller in more thickly populated districts acts as a barrier to the ready acceptance of new ideas. May I suggest this to the nurse. If she will take time to explain to the farmer in his own language *why* he should do, or not do, a certain thing she will find him the most cooperative person in the world. Try to highhat him or dictate to him and he will balk. For one I shall be glad when the work of these nurses has removed from the minds of country people the mystery that still surrounds illness and the idea of magic that they associate with healing.

It is our duty as physicians and health workers to instruct the public in health matters and to keep them informed about health conditions in our communities. Here the local newspaper becomes useful. I feel that the local health item carries much more weight than the syndicated article. It is a personal message of a local physician to local people many of whom are his patients. For this reason these articles do a lot of good. But if we are to catch the attention of the public and hold it they must be timely. An article on frost bite during the dog days of August is distinctly poor publicity technic. The subject for an item is often suggested by

some local condition. The threat of a scarlet fever epidemic may be causing some apprehension. Here is the chance to give people the news of the epidemic and at the same time tell them what they need to know about scarlet and how to avoid it. At the moment an article on scarlet is news. Because it is news the local papers welcome it. Because it is news it will be read.

In community organizations, such as Parent Teachers, we not only teach health but we train missionaries who will teach to others what we have taught them. Here is the big chance to mold public opinion—resentment against those who ignore quarantine and spread epidemics, who send children with whooping cough to school, who cough and sneeze their flu germs in churches and theatres. These groups are usually from the more intelligent of the community. It is here that the abstract discussion of health problems comes into its own. Here you can talk freely of your aspirations in community health. They will be interested in the gains resulting from free milk in schools. They will understand why immunization to diphtheria can never stop. You can quote figures and show a graph or two. To them you can talk about syphilis and even the National Broadcasting Company cannot stop you. With these groups the admonition to teach simply does not hold to the same degree that it does in the schools and in the press but it is just as well to remember that we are talking about things that are for the most part strange to them. Even in these groups our teaching often has to be as "little steps for little feet."

The movie in the country high school is another means of reaching the hard to reach farmer. In my town we have had films and we have had talks on syphilis. The idea was to prepare the way for the drive against that disease. I feel that the results were good. These meetings broke the ice. If you want to find the place where ultraconservatism still exists, where the ancient taboos are still in full force go to the small town. In my country syphilis and gonorrhea are still spoken as the "bad disease" and at low breath showing that we countrymen think of them in terms of morality and not as communicable diseases. But your farmer,

ultraconservative as he is, who learns how these diseases are increasing and how terrible are their effects and how other countries are checking them immediately wants to know why we cannot do the same. There is a field for health education through the movies not yet touched.

In spite of all our experience at health education we are venturing into a new field. In health publicity we are blundering about presenting statistics, issuing warnings, and predicting dire disaster to any who do not do as we tell them. The results have not been all we could hope for. The trouble is that we do not know the proper psychological approach. We have not developed a technique. We have not been very ingenious. In the past most of our slogans—and I think that slogans are dangerous things—have had little popular appeal. The one outstanding exception to this is the slogan devised by Dr. Biggs years ago "Public health is purchasable." Within natural limits every community can determine its own death rate. What an advertising man he would have made! In the hope of better results from our efforts I may suggest that we begin by being honest with ourselves and disabuse our minds of the idea that we reduce the morbidity or mortality rate by so much. We did nothing of the kind. The fact of the matter is that all the results we have obtained have been in direct proportion to the response we have obtained from the layman. We can only point the way. Unless he follows the results are nothing. I urge that in our teaching we use the language of the common man. It is not the language of scientific medicine but it is colorful and he understands it. We need to be positive in our statements. It may be objected that this is not always possible. Only occasionally is this true. We need to remember that the layman has a very great contempt for the qualified statement of the scientist. With country people we must never forget to give the reason why. People will cooperate in things they understand but dictation arouses opposition. "E's ist verboten" is not in the American vocabulary.

I feel that the greatest single defect in our health educational work is in that we expend so much effort to educate adults. Some of them can be educated, some do

not care whether they are educated or not and some refuse to be educated. All this time there are millions of children who can be so trained that they will live longer and happier lives. I would like to see children, from the time they enter school until they finish, given continuous health instruction. They can be made to develop health habits that would remain fixed for the remainder of their lives. And if they develop a contagious disease I would like to see them considerate of

others, show a spirit of good sportsmanship, and confine the infection to themselves. They need to be trained in the ethics of illness.

I want to make it plain that this is nothing but a few random remarks by a country doctor. The opinions expressed are entirely my own. Back of them there is no authority other than my own experience. Public health problems as you see them may be very different. This is offered for what it may be worth to you.

GRADUATE FORTNIGHT OF NEW YORK ACADEMY OF MEDICINE

Plans have been completed for the New York Academy of Medicine's Eighth Annual Graduate Fortnight. The subject for this year is to be "Diseases of the Respiratory Tract." The program is scheduled for October 21 to November 2.

Registration for attendance will be closed when the number reaches 700. Last year many who had planned to attend were disappointed at the last moment through failure to register. A fee of \$3.00 admits the holder to all the features of the Fortnight. Application for registration should be made to Dr. Frederick P. Reynolds, Medical Secretary, New York Academy of Medicine, 2 East 103 Street, New York City.

Eighteen important hospitals of New York City will present coordinated afternoon clinics and clinical demonstrations in connection with the program. Recognized authorities in special lines of work are to discuss various aspects of the general subject at evening meetings. A special effort has been made on an exhibit which will present a comprehensive picture of anatomical, bacteriological and pathological specimens and research material.

Among the features to be presented at the meetings, in the clinics and in the exhibit, will be:

The problem of asphyxia. Apparatus for resuscitation. Poisonous gases. Gas masks. Allergy in its relationship to diseases of the respiratory tract. The common cold. Influenza. Lobar, lobular and bronchopneumonia. Chronic pneumonia. Diseases of the mediastinum. Bronchiectasis. Pneumokoniosis. Emphysema. Sinus disease from infancy to old age. Diseases of the larynx, trachea and main bronchi. Whooping cough. Atelectasis and massive collapse with their concomitants, cyanosis and dyspnoea. Foreign bodies and tumors. Mycotic infec-

tions. Pleurisy. Asthma. Thrombosis and embolism. Abscess and gangrene. Pulmonary tuberculosis. Medical and surgical approach to empyema. Surgery of the chest. Postoperative pulmonary complications. Clinical and laboratory diagnostic methods. Drugs, sera, vaccines and other forms of therapy.

Speakers at the evening meetings will include Drs. J. Burns Amberson, George Blumer, Henry Chickering, Lloyd F. Craver, Alphonse R. Dochez, Leroy U. Gardner, Yandell Henderson, Charles J. Imperatori, Chevalier L. Jackson, Adrian Lambert, Howard Lillenthal, Harrison S. Martland, Jonathan C. Meakins, James Alex. Miller, Charles T. Porter, Maximilian A. Ramirez, Arnold R. Rich, David Riesman, Charles Hendee Smith and Henry Wessler.

The Graduate Fortnight originated in 1928, as a result of the activities of the Committee on Medical Education of the New York Academy of Medicine. One specific subject is selected each year and treated from its various aspects. Subjects of previous fortnights are: 1928, "The Problem of Aging and Old Age;" 1929, "Functional and Nervous Problems In Medicine and Surgery;" 1930, "Medical and Surgical Aspects of Acute Bacterial Infections;" 1931, "Disorders of the Circulation;" 1932, "Tumors;" 1933, "Metabolic Disorders;" 1934, "Diseases of the Gastro-Intestinal Tract."

An examination of the list of registrants for past fortnights shows visitors from every section of the country. It is interesting to note from these records that in a number of years other states have provided a greater attendance than New York State. For example, last year more physicians attended the Fortnight from Pennsylvania than from New York State.

VITAMINS AND THE CHILD

CHARLES G KERLEY, M D, *New York City*

Previous to the beginning of the present century, but a limited knowledge had been acquired concerning the chemistry and the utilization of food by man and animals. It was known that animal life required fat, protein, carbohydrate and mineral salts, fat and carbohydrates to produce heat and energy, protein for growth and developmental purposes, and mineral salts for bone formation and maintenance of nerve balance. These substances are taken in different forms depending upon the type of animal to be nourished. The herbivorous cow exists on a diet grossly much different from the carnivorous cat family, yet the basic nutritional factors necessary are the same for both types. The nature of the foods of different species vary, and the digestive apparatus of each specie is built to care for its peculiar type of nourishment and thus comprised our knowledge of the inter-relation of chemistry and body growth. That this covered and completed all that relates to nutrition has never been accepted by the biochemist and research worker. Since the time of Hippocrates (B C 460-370) there has existed in the minds of many investigators the opinion that there were unknown substances in foods that have an important influence in determining their utility. Hippocrates named the substance "Aliment."

During the next 2000 years but little was learned concerning the science of nutrition. A study of food and food values, and the effects upon the organism was first undertaken in a scientific fashion in the late seventeen and early eighteen hundreds. During the past twenty-five years, vast advancement has been made as to the relation between growth development, bodily disorders and the food consumed. It was found that chemically pure mixtures of the well known nutritional elements mentioned above failed to ward off disease and supply adequate body nourishment. It was concluded that food prepared by nature contained the necessary substance and must consequently carry other essential food factors

that possess the powers of activation, something that gave the necessary push to the food or the body cells to make the food utilizable by the physical organism. Late in the 1890's Kijlman, a Dutch investigator produced polyneuritis in pigeons by feeding polished rice and later cured them by feeding the husks of the rice removed in the polishing process. This observation stimulated research along nutritional lines in many countries. It was soon found by different investigators that something was needed and was present in food other than the well-known nutritional elements. These substances were described as accessory food factors. Funk in 1910 established that extracts made from rice polishings would cure polyneuritis in pigeons and coined the name "Vitamin" for this product. Later observations have shown the existence of five different vitamins* in nature and while the exact compositions of these substances have not been established, observations on humans and experiments on animals have made possible a differentiation among vitamins. Not only polyneuritis but scurvy, rickets, and an eye disease known as xerophthalmia, in addition to other ailments and tendencies are produced by deficient vitamins in the diet which vary in function sufficiently to enable us to make a broad classification. They are recognized as Vitamins A, B, C, D, and E.

Vitamin A—(fat soluble) Present in the fats of milk, egg yolk, cod liver oil and liver. It also exists in the husks of certain seeds and in the leafy vegetables. Scarcity or absence of this vitamin has a pronounced effect upon growth and development. Animals deprived of it experimentally show stunted growth, retarded development and the eye disease known as xerophthalmia already referred to.

Vitamin B—water soluble (vitamin B complex) Turnips, carrots and potatoes are particularly rich in this vitamin. It

* For technical chemical reasons the spelling was later changed to omit the terminal "e" and the present best form has become 'Vitamin'.

exists also in the leafy vegetables, in yeast, and in the seeds of plants. In addition to the production of the disease known as beriberi or polyneuritis a deficiency of vitamin B causes malnutrition, loss of appetite, a lack of bodily resistance and an absence of capacity for work. A child on a diet deficient in vitamin B will be looked upon as indifferent and lazy in an occupational sense. Further, children to whom this vitamin is furnished in inadequate amounts are predisposed to infection such as tuberculosis and the so-called common colds, which condition is nothing more or less than a bacterial infection of the mucous membrane of the respiratory tract. While many of such children have been freed from tonsils and adenoids, and the absence of sinus disease has been proven by competent observers, the colds still continue. An inquiry into the dietetic habits of such patients shows that because of the child's food dislikes or family indifference the food consumed is short in vitamin B, consisting of soup, meat, white bread and cereals ready to serve—usually the child hates the whole grain cereals and green vegetables. Further, I find that in the frequent cold cases, sugar is usually given in generous amounts. The use of a high sugar diet and a scarcity of vitamin B foods explain many cases of frequent colds for which the parents seek the aid of a physician.

Vitamin C: This is known as the anti-scorbutic vitamin, and is found in the citrus fruits, tomatoes, milk, and in other foods in lesser amounts. The disease scurvy has been recognized for hundred of years. In time of famine and war it has been responsible for the loss of thousands of lives. Until a few years ago it was frequently encountered in infants and young children. The potency of vitamin C is destroyed by heat. Bottle fed children who are given sterilized milk and the boxed baby foods supply the cases. A joint will become sore and painful, the gums show a blue margin adjoining the teeth and later bleed upon manipulation. Perhaps blood will appear in the urine. If the disease is not early recognized the joints will become excruciatingly painful and swollen, hemorrhages take place in the joint structure, sub-periostitically in the long bones. Infants fed on cooked or pasteurized milk, or the pro-

prietary milk foods should be given orange juice or tomato juice, both of which are at all times available.

Vitamin D: Exists in animal fats, such as cod liver oil and butter fats, and its absence or mal-assimilation is one of the principal factors causing rickets.

Vitamin E: Observations on this factor are not as well established as in the case of those discussed. Competent observers believe that it has a function in fertility and reproduction. It is found in the wheat germ, yellow corn and, leafy vegetables.

Such briefly for the vitamins known and accepted. What is the practical application of the findings of many able research workers in nutrition covering the past twenty years? Simply this—in selecting foods for the young, keep as close to nature as possible, use cows milk, butter and cream, cereals such as supplied by the whole seed crushed or ground, oats, yellow corn and wheat; vegetables as they come from the earth. Establish the habit of fruit and fruit juice consumption, give meats, poultry, fish and eggs in moderation. The results of narrow dietetic practices whether by habit or intent, devitalize the body, prevent normal growth and produce physical inferiority. Further and most important, resistance is broken down against those diseases in which a specific immunity is not supplied by the body cells.

Comment

All the essential vitamins are abundantly supplied by nature. Normal dietetic habits in children with a range of food as above outlined will obviate to a large degree the necessity of the artificial vitamins. The child who cannot take milk or milk products, or with whom fruits do not agree, who hates cereals or vegetables, and whose likes and dislikes determine his nutrition are to be numbered among those in whom the vitamins of the laboratory are necessary.

132 WEST 81ST STREET

RIGHT TO THE END

A violent dispute in an operating room over a point of surgical technic led to a duel with cavalry sabers between two surgeons in Budapest, Dr. Laszlo Farkas and

Dr. Josef Krauss of St. John's Hospital, according to a news dispatch. Dr. Krauss was critically injured. The dispatch omits to say what happened to the patient.

BACILLARY DYSENTERY

Acute Fulminating Type with Marked Toxic Neutropenia

JOSEPH FELSEN, M D, *New York City*

In another article¹ five atypical forms of acute bacillary dysentery were described, namely the appendicular, neurotropic, afebrile, asymptomatic and constipated. During the past six months three instances of another type has been encountered which, because of the uniform and distinctive clinical picture, is deemed worthy of note.

All three patients were women aged 26, 34 and 35 years, respectively, and came under observation shortly before death. The previous history covered a period of approximately four weeks during which time there had been present a severe diarrhea with blood and mucus accompanied by tenesmus, abdominal pain, and marked prostration. The pyrexia varied about 102° F to 103° F. Physical examination at the time of observation as specified above revealed in each instance an acutely ill patient suffering from what appeared to be an overwhelming toxemia. The features portrayed anxiety with pinched faces, flushed and somewhat hollowed cheeks and temples and labial herpes. The pulse was rapid, skin dry and there was evidence of generalized dehydration. The mentality was quite keen. Anorexia was marked. The chief symptomatology was directed to the abdomen which was greatly distended and diffusely tender. No rigidity was noted. Proctoscopy revealed an acutely inflamed ulcerated mucosa, bleeding freely to the slightest trauma and exuding a mucopurulent fluid. The ulcers were shallow, irregular in shape, discrete or confluent, occasionally serpiginous, but were not undermined or surrounded by a hemorrhagic halo. The intervening mucosa was diffusely inflamed and the site of patchy membranous deposits. There was an almost continuous flow of fluid fecal material mixed with mucus and blood. Here and there the intact mucosa showed definite evidence of an acute inflammatory polyposis (polyposis cystica of Virchow). Cultural, agglutination and phage studies instituted at this time revealed the

infections to be due to *B. dysenteriae* Sonne-Duval, Flexner and Mt Desert, respectively. No trophozoites or cysts of the *Endamoeba histolytica* were found. The blood picture in each instance was that of a severe progressive leucopenia, the count falling to 1200 leucocytes per cu mm or below. The neutrophils totaled less than ten per cent, the remaining cells being lymphocytes. Varying degrees of toxic change were noted in nearly all of the polymorphonuclears such as swelling of the cell bodies, coarse irregular cytoplasmic granulation with vacuolization and focal pyknotic areas in the nucleus with partial or complete disintegration. In one case the leucocyte count rose just prior to death to 6400 with a corresponding increase in the neutrophils. This may have been due to intensive antidyenteric serum and vaccine therapy instituted shortly before the rise occurred. The relative and absolute granulocytopenia is of particular interest because leucopenia is quite characteristic in the early stage of many cases of acute bacillary dysentery which we have encountered, often falling as low as 4000. The differential count, however, is normal or near normal with little evidence of toxic change in the neutrophils. With convalescence, a gradual rise to normal or a moderate leucocytosis occurs. The blood picture described above may be due to the destruction of granulocytes in the peripheral blood stream or to the necrotizing action of dysentery toxin on the vascular sinusoids of the bone marrow. The granulocytes cannot migrate from the extravascular zone in the bone marrow where they are formed into the blood stream. Sections of the bone marrow in one case showed no deficiency of granulocyte production. We have repeatedly noted vascular necrosis in necropsy specimens of the intestine and spleen in acute bacillary dysentery.

The clinical course of the three cases referred to was rapidly downhill, perforation and peritonitis occurring in each

instance twelve to twenty-four hours before death. An antemortem pyrexia of 106° F. or above was also noted. Post-mortem examinations made in two of the three cases reported showed an extensive ulcerative enterocolitis with polyposis involving the distal portion of the ileum and the entire colon. The course of the acute infection in each case was approximately one month.

Certain clinical inferences may be drawn from this unusual type of dysentery. The presence of herpes which we previously noted in the neurotropic form of dysentery suggests a combined form of two toxins,—the enteric and neurotropic, a virus probably being associated with the latter. From our preliminary clinical and experimental work in other cases it also appears that there are at least two other fractions or individual toxins which have an affinity for the bone marrow (myelotoxic) and joints (arthritic). All of these toxin factors must be taken into consideration in selecting the toxin producing strains for immunizing horses. The inefficacy of therapeutic antidysenteric serum used early in some cases is undoubtedly due to the neglect of this important point. For therapy to be effective the disease must be recognized in the early stage and high titer polyvalent dysentery antitoxin given at once. It is of value chiefly within the first few days of the disease when the ulcerative lesions are being produced during the process of excretion of the toxin from the blood stream through the wall of the bowel into the lumen. Once the damage has been done, and the major portion of it appears to occur within 24 to 72 hours,

serum or antitoxin can only arrest further action of the toxin. Secondary non-specific intramural infection may occur through the ulcerations produced by *B. dysenteriae* and the field is set for chronic dysentery in the forms more widely known as chronic non-specific ulcerative colitis, chronic distal ileitis or non-specific granuloma.² Repeated fecal cultures must be made during the first few days. Agglutination titer and diagnostic bacteriophage are usually of value during, or after, the third week. A severe diarrhea, possibly traceable to a very recent (12 to 48 hour) contact infection, moderate fever, tender, spastic ileum and sigmoid and a normal or subnormal leucocyte count are sufficient indications for instituting specific therapy without waiting for the results of fecal culture. This is particularly true of infants and children.

Summary

A form of acute bacillary dysentery has been described, characterized by a rapid course, progressive leucopenia with granulocytopenia, and fatal termination in approximately one month. The importance of early diagnosis and immediate specific therapy with high titer dysentery antitoxin is stressed.

CAMPAIGN AGAINST DIABETIC DEATHS

Many unnecessary deaths from diabetes are occurring every year, due to ignorant self-medication, says Health Commissioner John L. Rice, and he is sending a letter to all New York City physicians asking data on their diabetic patients. It is said there are 100,000 diabetics in the city. Information sent to the doctors also states that—

"Approximately twice as many women have diabetes as men.

"Diabetes appears more frequently in persons over forty-five years of age.

"The disease is more prevalent among Jews than among non-Jews.

"It is two or three times more prevalent among married women than among unmarried women of the same age.

"Since the introduction of insulin in the treatment of diabetes there has been a distinct prolongation of life of diabetic individuals.

"Contrary to statements often made, diabetes was always a very prevalent disease, only it was not so frequently correctly recognized in years gone by.

Social Suicide

Speaking at the Annual Convocation of Colgate University, President Cutten issued a warning on current social trends that should receive the serious consideration of leaders in government and sociology. Many of the checks imposed by nature on the unfit have been removed by modern civilization without the imposition of compensatory controls. The result is a biological anarchy which must be stopped, according to Dr. Cutten, "for a civilization which removes natural checks more rapidly than it fosters higher controls commits suicide."

Social legislation draws special fire from Dr. Cutten because it encourages "the fit to join the ranks of the unfit." This does not mean that welfare measures should be abandoned but that they should be so devised as to aid the unfit without increasing their number or corrupting the fit.

Compulsory health insurance is an outstanding example of the legislation condemned by President Cutten. It reduces to a state of partial dependence many who have always provided for their primary needs and encourages malingering by placing a premium on illness. Regular deductions from the small wage earner's salary make it almost impossible for him to save, thereby fixing him permanently

in the under privileged class. At the same time the economic status of the physician is lowered and his professional independence impaired.

The end result of this reform, then, is a working class which has lost its self reliance and its chance to rise, a medical profession deprived of the incentives for research and self improvement, an inferior brand of medical care and a staggering burden of taxation to maintain a superfluous bureaucracy. Dr. Cutten does not exaggerate when he calls such a condition social suicide.

Counter Curbs

The State Department of Health should re-examine its powers to see whether it has not the right to curb the unsupervised sale of many drugs now in common use. It is impossible to estimate exactly the damage to the public health from excessive use of preparations now purchased over the counter, but there is no doubt that some untimely deaths—to cite just one example—result from the misuse of aspirin and coal tar derivatives.

The mischief does not rise solely from dangerous properties in the drugs. While reducing preparations with dinitrophenol and depilatories containing thallium acetate should be barred *per se*, there are other products which are safe and useful

in the hands of a physician but not to be entrusted to laymen. This group includes glandular extracts of all types, atophan, veronal and a host of other pharmaceuticals.

Apart from these considerations, there is the delay in seeking necessary treatment which results from self-medication,—a delay which usually prolongs the period of illness, extends the pathology and may cause chronicity or even death. The numerous pain-killers on the market frequently veil the early stages of a dangerous lesion which, once advanced, is incurable.

The physician is not wholly free from blame in this situation. By ordering proprietaries instead of writing prescriptions he has made certain preparations familiar and seemingly safe to the public. A more important factor is the widespread advertising of commercial drug houses.

The practitioner can help a little by reviving the art of prescription writing. Until adequate legislative curbs are placed on the advertising of drugs and cosmetics, however—and that day seems regrettably remote—there seems little hope of persuading a large section of the public to visit the doctor before the druggist. The Department of Health can minimize the dangers of self-medication by forbidding the sale of potentially harmful drugs except on prescription.

Economic Problems of Medicine

There has appeared a short, concise, easily-read volume on economic problems of medicine from the pen of Dr. A. C. Christie which is so well balanced and comprehensible a book that we recommend it to our members. It carries lessons for hospital workers and social workers. Those who have adopted compulsory health insurance as their own will learn much from it, and the organized profession will find comfort and inspiration for the standpoint it has held by the data presented by this student. We particularly recommend it to our legislators who will soon be confronted by the confusing

claims of proponents of so-called social medical reforms because it is not only entertaining but highly instructive and authoritative.

Another Survey

The Federal Government, through the agency of the Public Health Service, is about to undertake a survey of sickness in this country. To what purpose the accumulated data will be put has aroused a sensitive profession so that it is on its guard. Who asked for this survey? What useful purpose is to be accomplished by the large expense involved? The taxpayer, of course, must again meet the burden.

We know from bitter experience how surveys eventuate into propaganda. Who needs this propaganda? Or are we to consider this as another government project, paid for by taxes, to be developed as it goes along and eventually to be used in an effort to regiment the profession and socialize medicine? How medicine longs for a real long breathing spell!!

Meningococcic Meningitis

For more than a quarter of a century, anti-meningococcus serum has been accepted generally as the proper therapeutic agent for epidemic cerebrospinal meningitis. The method of employment, however, varies widely in the hands of different practitioners. Some favor the use of massive doses intraspinally; others, frequent administration, sometimes as often as three times daily in combination with intramuscular and intravenous injections of the serum. This wide difference in the employment of the serum is probably due to the general misconception that the serum destroys the organisms in the spinal fluid. From all knowledge at hand, it appears that the serum is definitely not bactericidal, and at the present time little is known concerning the exact manner in which the serum acts to cure the lesion.

Because of these factors, in addition to the wide variance in the clinical mani-

festations presented by the disease in different epidemics and in different individuals, Neal¹ states that no one standard means of therapy is to be advocated. The serum should be injected intraspinally in all cases, but intravenously only when a positive culture of micro organisms is obtained from the blood stream. Only where the intraspinal pressure is very high should a lumbar puncture be performed more than once in twenty-four hours, since, in the removal of the spinal fluid, leucocytes are withdrawn which still possess their utmost of phagocytic power.

From experience gained in the study of epidemic meningitis over a period of twenty-five years, Neal feels that the best results in the treatment of meningococcus meningitis are obtained by the proper application of serum therapy to the clinical type of case presented. The usual cases of the disease should not be treated in the same manner as the septicemic or fulminating ones and moderation in the use of serum is more often than not followed by the most favorable result.

The Common Cold

The common cold is the one disease concerning which the lay public and the manufacturers of patent medicine profess to know more about than the medical profession does. One has but to sniffle or sneeze and he is immediately showered with the solicitous advice of his friends as to the multitude of sure cures available. In addition, he has before him constantly the "educational" program of the makers of remedies for coryza. Is it any wonder, then, that the farmer, having tried all the means suggested to him, was finally led to state that "the best thing for a cold is a handkerchief?"

But of far more importance is the prevention of the common cold, which, in many instances, assumes epidemic proportions and is attended with many severe complications. The failure hitherto ade-

quately to cope with the rapid spread of the infection through a community has been largely due to our almost complete lack of knowledge concerning the exact etiological factor. It is extremely doubtful but as yet undetermined whether or not the pathogenic organisms which ordinarily inhabit the upper respiratory tract are the causative agents. It is, however, an established fact that they do play a role in the development of the various complications.

Recent work on this subject seems to indicate that the causal agent of the common cold is not present previously in the nasal passages of those who are attacked. Sterile filtrates made of the secretions of individuals who are in the first stage of a cold will reproduce a cold when instilled into the nares of humans who have been free from and quarantined against the disease. This filter-passing agent is capable of surviving for a long period outside the body and will proliferate *in vitro* upon suitable culture media.

Browning,¹ in a survey of the more recent investigations anent the common cold, feels that the evidence brought forth points strongly toward the introduction of a filter-passing agent into a previously healthy person as the manner in which that person contracts a cold. The outbreak of an epidemic of colds in a community after the visit to it of a stranger who has a coryza furnishes additional support for this contention.

CURRENT COMMENT

THE BULLETIN OF THE Bronx Medical Society, issued in September, says that a dramatized radio program will be offered over the Blue network of the National Broadcasting Company, beginning October 1st at 5 P. M., Eastern Standard Time, and continuing on every Tuesday thereafter. This program is sponsored by the American Medical Association and we feel that this first national radio attempt to publicize

¹ Neal Josephine, B. Meningococcic Meningitis in Children, *J. A. M. A.*, Vol. 105, No. 8 P. 568, August 24, 1935.

¹ Browning, C. H. The Common Cold, Survey of Recent Work, *Glasgow Med. Jour.*, Vol. 5 P. 329 June 1935.

organized medicine should be brought to the attention of patients as well as the profession.

THE SEPTEMBER BULLETIN OF THE Monroe County Medical Society, speaking of the new compensation situation says, "Since the beginnings of medical history, it has been a melancholy but indubitable fact that medical authority has had to struggle constantly with those who opposed its right and competency to take care of the sick. * * * For nearly a generation of time an outstanding social endeavor of our state, with reference to the injured of industry, has functioned with a definite degree of success but with certain imperfections that have been attributed to lack of adequate medical representation. The new law awards to the profession a wholesome opportunity and a heavy responsibility. The opportunity consists in being granted a set-up which recognizes the equal rights of every licensed physician to take care of certain injured individuals. * * * The responsibility resides in the fact that the profession should familiarize itself with the problem, should function wisely and should not abuse its increased power."

FROM THE WESTCHESTER MEDICAL BULLETIN of September we cull, under the title, "Too Proud to Fight?," the report of a survey regarding the social prestige of the medical profession made by Professor Hartmann of the Pennsylvania State College. It says, "It should be a source of satisfaction to the public, almost as much as to the profession itself, that medicine is still by far the most highly respected of professions and occupations. * * * Fortunately, the tendency toward the corporate practice of medicine which was very strong a few years ago now has been quite effectively repulsed, largely through the effect of

a few unequivocal court decisions and the stiffening resistance of organized medicine. There is even now, in New York State, a bright chance of regaining some of the lost ground, by means of the new Compensation Law and the current action against the Life Extension Institute. * * * The most certain way for the physician to destroy his social esteem would be to permit his economic status as an independent servant of the sick to be destroyed."

AT A MEETING IN New York on August 13th, the American Child Health Association discontinued its activities. The reason for this lay in the fact that the aims and purposes for which the Association was formed have been, in large part, accomplished. This was the gist of the presidential address made by Dr. Samuel M. Hamill of Philadelphia.

IT HAS BEEN LEARNED that the topic which has been selected for debate among over one hundred thousand high school boys and girls in thirty-one states is to be the following: "RESOLVED, that the several states should adopt a complete system of medical care available to all people, at public expense." The subject of the debate has been fostered by both the Rosenwald Foundation and the Pollak Foundation as a continuation of their hitherto unsuccessful efforts to bring about the socialization of medicine. These young debaters will, in some instances, turn to members of the profession for advice and counsel as to how to conduct the debate and it should be the purpose of every one to help them formulate their ideas. We are in accord with the suggestion made by the Westchester County Medical Society that the County Society should and undoubtedly will take steps to supply the debating leagues with reliable information and data.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network:

Thursday, Oct. 17, 1:15 P.M.—*Speaker:* Dr. William B. Parsons, Assistant Professor of Surgery, Columbia University. *Subject:* "Goiter."

Thursday, Oct. 24, 1:15 P.M.—*Speaker:* Dr. Robert H. Kennedy, Surgical Director, Beekman Street Hospital. *Subject:* "Broken Bones."

Thursday, Oct. 31, 1:15 P.M.—*Speaker:* Dr. William Crawford White, Associate Attending Surgeon, Roosevelt Hospital. *Subject:* "Progress in Cancer."

Thursday, Nov. 7, 1:15 P.M.—*Speaker:* Dr. Samuel J. Kopetzky, Professor of Otolaryngology, New York Polyclinic Medical School. *Subject:* "Exploiting the Deaf."

Patient: "Doctor, I feel like killing myself. What shall I do?"

Doctor: "Just leave it to me."

A New Racket

416 OCEAN AVENUE
BROOKLYN, N. Y.

To the Editor:

It will interest the medical profession in and around New York to know that a new form of racketeering by unscrupulous and debased physicians is being practiced upon their fellow practitioners. At least the writer, in over a quarter of a century of practice, never heard of this scheme before and only learned of it recently when he became a near-victim of it. The racket is based on the typical gangster "paying for protection" method and may be termed "case piracy." Whereas the fee-splitter (assuming that fee-splitting exists, although questionnaires in and out of medical societies would prove that "no doctor, anywhere, has ever heard of such a thing") makes his "claim" on the ground of what he has done for the doctor to whom he has referred a patient for operation, the case pirate demands payment for what he has refrained from doing to the doctor. The fee-splitter does have some connection with the patient; the pirate simply chisels in on a case with which he has no connection—often not even knowing the patient's name—and demands tribute in order "not to spoil the case for the doctor," meaning that he would deliberately besmirch the doctor to the patient and "steer" the patient somewhere else. There is no doubt that a low-down snake of this type is capable of doing it. When the physician is approached by such a crook, the fact that he knows about the case leaves the physician in a quandary as to just how close to the people this individual really is.

Having recently been the near-victim of this scheme I have found out how it works.

Suppose a Mr. A is a patient of Dr. B. A needs anectomy, but is waiting for either the time or the money to go through with it. Perhaps he is putting it off until his vacation or for his wife to return or to sell something with which to raise funds. Let us say he is a clerk in a cigar store or he runs a grocery store; he is also quite talkative and is telling many of his customers about the operation that he is going to have done. Among these customers is a Dr. X or a Dr. Z who, when

he hears about it, finds out, casually of course, the surgeon's name who is going to do the operation. The patient, Mr. A, may have been going to the doctor for weeks or months previously, but that doesn't mean anything to the pirate. He immediately calls up Dr. B on the phone and tells him that he is "in a position" to work with him on Mr. A's case—for a consideration (the inference being that just as he can boost him, he can also knock him). In the attempted extortion of the writer, the pirate was quite frank about being able "to spoil the case." Knowing how some patients can easily be influenced by others, especially by another physician, the unsuspecting doctor is likely to "come across." If the pirate actually knows the patient he may prevail upon the patient to insist on bringing him along to Dr. B when he goes there—thereby proving to Dr. B the advantage of "being in with him." . . .

In my experience of this attempted extortion by this piratical crook who tried to chisel in on the case six weeks after the patient had originally come to me and who had been referred by another man as well as by another patient, I discovered afterwards that the patient had never sought the crook's advice as to my surgical qualifications and that the crook himself didn't even know his last name. He only knew his first name. Yet he had the effrontery to come in person to my office to prove to me "his side of the case" that he was entitled to a fee for his part in NOT spoiling the case for me. It was much like the condemned man who is taken away to the electric chair who is talking over and over again to his friends because "he had been fair" to them. His victim: he had given them a chance before shooting him down. The distortion is evident in these circumstances.

I might add that this crook was a member of his county medical society connected with a certain hospital (Shades of Mephistopheles). What about the medical practice of this

Society Activities

Malpractice Insurance Committee

The Yorkshire Indemnity Company of New York has been selected as the carrier of the Group Malpractice Insurance Plan of the Medical Society of the State of New York beginning January 1, 1936. All new certificates under the Society's master policy dating on or after January 1st will be issued by the Yorkshire. The Aetna Life Insurance Company will carry to expiration all policies issued by that company, that is, all policies in the Aetna issued up to and including December 31st of this year will be carried by that company until they expire in 1936, at which time they will be renewed in the Yorkshire.

For the benefit of members who would like to know something more about the Yorkshire, your Insurance Committee offers the following report:

The Yorkshire Indemnity Company is a New York corporation organized under the laws of this state in 1926. It is not a large company as compared with some of the great companies of today, but it has over \$2,000,000 of sound admitted assets in this state.

However, the test of the security which a company offers to its policyholders does not depend upon size, but upon good underwriting, sound and economic management, adequate reserves for undischarged liabilities of all kinds, adequate net resources, sound investments and dividend policy. A large company may be in a questionable situation with respect to some or all of these items and, therefore, offer doubtful security to its policyholders, while a small company may be so strongly organized, financed and managed as to offer the best possible security to its policyholders. The Yorkshire Indemnity Company falls in the latter class as clearly indicated by the rating given it by Best.

The Alfred M. Best Company of New York is generally accepted as the leading authority in the country on insurance company ratings. Its analyses cover every detail of organization, financial position, reserves, management, etc., and are reduced to ratings

running from A for excellent to E for poor. In addition, it reclassifies those companies in each rating group which are above the average of such group and adds a plus sign after the rating letter. Thus, A+ is the highest rating that can be given to any company, and assures to the policyholders the strongest possible security behind their policies.

Your Insurance Committee is glad to report that the Yorkshire Indemnity Company enjoys an A+ rating by Best, and that it has held that rating throughout the pressure of depression years which has tried the stability of much larger and better known companies, some of which have found it difficult to survive. In addition to this, the Yorkshire has behind it as a parent company the Yorkshire Insurance Company of England, one of the oldest and most conservative insurance companies organized in 1824 and transacting a highly reputable world-wide business with assets of over \$75,000,000.

It will be understood, of course, that all of this was given first and thorough consideration by the Society before the Yorkshire was designated as the carrier of the Group Plan. It is being published in this manner, however, for those members whose private insurance representatives have, for reasons best known to themselves, seen fit to loosely criticize the Yorkshire's position and to create doubts as to the wisdom of accepting its policies. Such criticism cannot be well informed or have as its object the malpractice insurance welfare of the members or the solidarity of the Group Plan as a whole.

Every phase of the Yorkshire's situation so far as it may apply to the Society's Group Insurance has been scrutinized and passed upon. Not only is the Yorkshire entirely sound as indicated by its general rating, but in the opinion of your Insurance Committee it offers under its agreement with the Society the best source of malpractice insurance protection obtainable.

CHAS. GORDON HEYD, M.D., *Chairman*

Committee on Public Health and Medical Education

The Committee on Public Health and Medical Education of the New York State Medical Society wishes to urge upon County Medical Societies the necessity for having an active committee on Public Health. It

is most desirable that some members of this committee be interested in pediatrics and health activities for children.

It is probable that Federal funds will soon be available for the State Department of

Health to expend on child health work. It is necessary, therefore, that County Societies be well organized to take the leadership in directing these activities, if physicians in active practice are to do the work and be compensated for it.

This Committee of the State Medical Society approve, the following and suggest that the County Medical Societies undertake as many of them as possible:

- 1 Pre School Examinations
- 2 School Health Programs
 - a Active cooperation with school health authorities
 - b Appoint advisory committee
 - c Improve forms used for examinations

d Physical Examinations by private physicians

3 "Children's Health Hour," in physician's office for health measures, including immunizations against communicable diseases

4 Intensive effort to improve the care of premature infants

The Sub Committee on Child Hygiene will be glad to act in an advisory capacity to aid in the development of your plans for the work outlined above.

Sub committee on Child Hygiene

FAIRFAX HALL M D *Chairman*

Minutes of Annual Conference of County Society Secretaries

DEWITT CLINTON HOTELL, ALBANY, SEPTEMBER 10, 1935

The following thirty three County Societies were represented:

Albany	Dr Nelms
Bronx	Dr Friedland
Broome	Dr Quackenbush (sub)
Cattaraugus	Dr Garen
Cayuga	Dr Maxwell
Clinton	Dr Wessell
Columbia	Dr Galster
Cortland	Dr White
Delaware	Dr Thomson
Frie	Dr Beamis
Essex	Dr Gau
Genesee	Dr Di Natale
Jefferson	Dr Prudhon
Kings	Dr Raphael
Monroe	Dr Mac Vay
Montgomery	Dr Pierce
Nassau	Mr Neff (Exec Secy)
New York	Dr Irving (Asst Secy)
Niagara	Dr George
Oneida	Dr Hale
Onondaga	Dr Sutton
Orleans	Dr Roach
Otsego	Dr Atwell
Rockland	Dr Ryan
Schenectady	Dr Shapiro
Schoharie	Dr Odell
Tioga	Dr Peterson
Ulster	Dr Gannon
Warren	Dr Maslon
Washington	Dr Banler
Westchester	Mr Bryan (Exec Secy)
Wyoming	Dr Klostermyer
Yates	Dr Hatch

Others present were Dr Frederic E. Sondern President of the State Society, Dr Edward G. Whipple member of the Public Health Committee, Dr Frederic E. Elliott Chairman of the Committee on Economics, Dr Harry Aranow, Chairman

of the Committee on Legislation, Dr James F. Rooney Trustee, Dr Thomas H. Cunningham First Vice President, Dr Charles Stover Past President, Mr Dwight Anderson Director of the Public Relations Bureau, Dr George M. Richards President of the Rockland County Medical Society, Dr Horace M. Hicks, Dr Edward C. Podvin and A. W. Bailey, D.O., members of the Industrial Council, Dr H. Jackson Davis Medical Director of the WPA, Dr George H. Ramsey Director Division of Communicable Diseases, State Department of Health, Mr Michael Murphy, Acting Director of Compensation Division, State Department of Labor and Dr Joseph S. Lawrence, Executive Officer of the State Society.

The Conference was called to order by the Assistant Secretary, Dr Peter Irving, who announced that Dr Dougherty, the Secretary, could not be present and in his absence he would act as chairman of the Conference.

The first speaker was Dr Edward G. Whipple representing the Committee on Public Health and Medical Education who outlined the drive that is to be made against pneumonia this winter. He stated that there is inclined to be a failure on the part of the membership of the State Society as a whole to appreciate the work of the standing committees. Membership on these committees means a sacrifice of time and money and the deliberations of the committees are in every instance of benefit to the membership. The Committee on Public Health and Medical Education is a very active com-

mittee, led by a chairman whose ability is only equaled by his enthusiasm. Among the many subjects recently considered by the committee, an organized effort against pneumonia has been most outstanding. A subcommittee, headed by Dr. Russell Cecil, has formulated plans, not yet complete, to cooperate with the State Department of Health, and possibly some private agencies, to lessen the morbidity and mortality from pneumonia. Any such effort by organized medicine necessitates on its part: (1) Willingness of the physicians of each County Society to assume leadership in their county in health matters; (2) An organized County Society including *at least* active and interested public health and public relations committees; (3) A medical profession well-informed on the subject of pneumonia. This latter necessitates an intensive and recent review of the subject. On the part of the State Department of Health, it is essential that they provide readily accessible laboratories and technicians and available sera for Types I and II pneumococcus pneumonia. In a review of the subject, physicians must know that there is a pneumonia problem; that 50 per cent of pneumonias are due to pneumococci; that 30 per cent of these are Type I; that mortality from Type I can be reduced 40-60 per cent by the giving of Type I serum sufficiently early, in sufficient doses, and sufficiently often; that it is *not* necessarily a useless procedure to give serum after the fifth day of the disease; that there is a Type II pneumococcus serum, probably as productive of results as Type I serum; that Type I serum is now available from the State Department of Health and it is hoped that Type II serum will be available very soon. Reactions will occur but can be met by the proper use of 1-1000 solutions of adrenalin chloride. Many may be avoided by reading carefully the instructions accompanying the serum from the State Department of Health or the manufacturer. Even though there is a delay in providing funds for a detailed effort against pneumonia, much can be done by each County Society, as leaders in health in their community, to conduct locally such an effort under the guidance of the Committee on Public Health and Medical Education of the State Society.

Dr. Ramsey, of the State Department of Health, stated that the Association of Public Health Laboratories offered to assist in the reduction of pneumonia mortality by making available for the practicing physicians facilities for employing the latest methods of type determination, and the State Laboratory is manufacturing the concentrated

serum which will be supplied to the laboratory produce distributing posts throughout the State. The department will cooperate further by distributing pamphlets and other educational material. Its full cooperation will be limited for the time owing to the fact that not sufficient funds were appropriated for the purpose by the last Legislature. There is some hope that the department may have its funds supplemented by gifts from certain voluntary, interested agencies. In cities of the first class the serum will be obtained through the local department of health.

For the effective direction of the State-wide program, a committee will be formed consisting of representatives of the Public Health Committee of the State Medical Society, the Association of Public Health Laboratories, the Department of Health, and certain other voluntary agencies. All of the speakers emphasized the fact that the success of the work depends primarily upon the wholehearted cooperation of the practicing physician. The diagnosis of pneumonia must be made early and serum treatment started immediately if success is to be achieved. Mr. Anderson, of the Public Relations Bureau, offered his assistance in publicizing the work. At the close of the discussions the Conference adopted the following resolution:

Resolved, That the secretaries of the component County Societies of the Medical Society of the State of New York, enthusiastically endorse the program of the State Society to reduce mortality from pneumonia.

At this point Dr. Irving read a telegram received from Dr. Dougherty expressing his regrets at being unable to attend the Conference and extending best wishes to his brother secretaries.

In the absence of Dr. Kaliski, who was to speak on the new Workmen's Compensation Law, Dr. Frederic Elliott, a member of the Special Committee on Workmen's Compensation, substituted for Dr. Kaliski. He stated that neither insurance companies nor employers in industry may post lists of authorized physicians. He stated further that he and Dr. Kaliski, at the direction of Dr. Heyd, have been conferring with representatives of insurance companies and employers of labor regarding a fee schedule, which the law provides shall be offered by the President of the Medical Society. He also reported that through conference with the State director of the WPA an arrangement is being developed by which physicians enrolled on the workmen's compensation panel will be employed and that injured employees will be given the same privilege of selection as is accorded industrial em-

ployees In speaking of the classification of physicians by County Societies, he called attention to a communication that had been sent by the committee to certain County Societies for reclassification and he urged that all communications from County Societies regarding the details of the law be addressed to the committee,—in other words, the special committee of which Dr Heyd is chairman, is a liaison committee.

There was some discussion as to how the reporting forms should be distributed whether by the Department of Labor or the County Societies through the secretaries. A number of the secretaries objected to the extra work that is being placed upon them, especially in light of the fact that most of them have no assistance and in some instances no extra funds have been provided for the incurred expense. That brought up the question as to how many of the County Societies are collecting extra funds for financing the work. It was reported that the following charges are being made: Two County Societies charge the registrants \$5.00, five charge \$3.00, seven charge \$2.00, one charges \$1.00, and sixteen of the secretaries stated that their Societies make no charge.

Dr Elliott, in response to a question as to the status of the medical bureau, stated that established bureaus may continue but that is not a license for new bureaus to open up. Moreover, if the employer insists upon conducting a bureau without a license, bring charges against the employer, if he is obtaining medical practice for a certain doctor, charge him with solicitation.

Dr Podvin, a member of the newly created medical division of the Industrial Council, stated that the Council took the addition of physician members very seriously. Employing his own words:

A subcommittee of which I am chairman has been appointed to deal with medical questions. When we went down to the first meeting we were rather shaky and thought the fellows might not agree with us on any subject. We have found them our most ardent supporters. In the subcommittee there are four members—Dr Linder, myself, Mr Meyer representing employers, and Mr Curtis representing labor. When we first started to discuss problems we found that the laymen on our committee not only were opposed to having in the poster permission to post names but insisted on putting in clause that names must not be posted. When it came to question of surrendering of choice of physician by the employee they were the ones that suggested this clause:

You may recommend the name of an authorized physician to an injured employee if requested to do so in writing after an accident. (Item No. 2)

You shall not ask for or accept a waiver from any employee depriving him of his right of free choice of an authorized physician before an acci-

dent occurs or at any time as a condition of employment. (Item No. 3)

Those were both put in there by the lay members. We felt that if we didn't do anything about the possibility of a serious accident there might be some question, so we included the following:

In the event of a serious accident requiring immediate medical aid an ambulance or any doctor may be called to give first aid treatment. (Item No. 6)

This is in the law now, any doctor can treat an emergency. First aid treatment is to consist of one treatment. This committee was appointed at the first meeting of the Council and I am going to discuss some of the points which were included in the report presented yesterday at the meeting held in New York City.

The first meeting of our subcommittee was taken up with the matter of arranging the poster, also the decision that all doctors whose applications had been disapproved by the various County Medical Societies, may continue to treat workmen's compensation cases until final decision is rendered by the Industrial Council. At a later meeting we took up the question of C-4 reports. This report is the one you make at the end of twenty days. That report should be notarized and the reason is that it insures the value of the report as prima facie evidence when filed in compensation claims. At that meeting we took up some of the rules of procedure for arbitration committees and discussed the question of the method of registration of the osteopathic and homeopathic physicians.

We devoted one meeting to hearing some of the representatives of hospitals. Hospitals feel that all services rendered in the hospital by the doctors is part of the hospital service. Your representatives on the Council backed up by the State Committee insisted that it is perfectly plain in the law that pay for compensation medical work shall be given only to the doctor rendering the services that x-ray pathology, anesthesia, etc. is the practice of medicine. You know it is very easy for us to sit down and come to an agreement as to what should be done but when you do it from the standpoint of a State Department you have to safeguard yourself not only against argument of right and wrong, but you have to safeguard yourself against any future legal action that may be taken to upset your decision. Therefore we decided to hold another session of this special committee at which representatives of the hospitals and our own committee will be present to thrash this thing out so that if later they want to make a test case they can't go into court and say they didn't have an opportunity to talk the thing out.

On the question of registered physiotherapist the committee recommends that a registered physiotherapist may treat workmen's compensation cases at his own office or bureau when the case is referred to him by a licensed physician. Authorized physician however should give written order to the physiotherapist as to kind of treatment and number of same.

Now about the removal of doctors from the panel as provided in Section 13-d by the Medical Society or board that has recommended

authorization of physicians. The committee drew up the following sketch: The doctor accused of misconduct shall be notified as to the date and time of hearing. A careful record shall be kept of the hearing. That record shall be submitted to the Commissioner. Now the matter is before the Commissioner and then comes the appeal. Appeals will be submitted to the subcommittee. The doctor appealing and the Medical Society or its board shall be notified in writing as to the date of the hearing. The doctor may be represented by counsel. Stenographic reports are to be kept and findings submitted to the Industrial Council.

As to question of arbitration: It is estimated that we are going to have a great deal more arbitrating under the new law than under the old. Under the old law many men had direct contact with the insurance companies and did not dispute the amount paid them by the insurance company even if lower than their original bill; or if they did dispute it very few cases came to arbitration because the doctors felt they did not want to offend the insurance companies. Now it is thought that there will be a great many cases. In the event of disagreement as to value of medical service rendered, hearings shall be held in the county in which the doctor practices or in locality where his office is located. It was thought that the State should be divided into districts; that is, the present industrial districts, of which there are five, so that when these hearings are held it might be by district instead of by county. Notice of the hearing shall be sent to the doctor who has rendered the service, the employer, and the insurance company, any one of whom may be present if he wishes. The arbitration board shall pass upon the case. Careful records of the hearing shall be kept in the office of the County Society.

I should like to speak about one or two things in the matter of the local boards which had refused to qualify certain men to practice under this act and afterwards seemed to get a change of heart and sent in their names. The members of the Council felt that that was a very poor practice. Therefore, the committee makes the following suggestions: That in the event of the rejection of a physician by a County Medical Society, the jurisdiction of the Society has terminated and it cannot reconsider its action. A man has the right to appeal, but the court set up by law is the Industrial Council and the appeal should go there and not back to the committee that has already passed upon it. In order to do this, each County Medical Society must pass upon an application within thirty days after its receipt and notify the Industrial Commissioner as to its action.

The committee suggests—and this was approved at the meeting yesterday—that bills for x-ray and other specialists be made out separately and be submitted by the doctor in charge of the case and paid directly by the employer to the doctor rendering the service. The doctor in charge is the responsible party. The bill of the specialist should be separate but should go in with the bill of the doctor, but the check for payment should come to the individuals who rendered the service. Upstate they have been sending in the bills in toto and when the doctor

gets the check sometimes he forgets about the other fellow.

There is one sentence in the law that a good many of the New York men seem to misinterpret; that is about authorization of a specialist—a man who receives in excess of \$10.00 or \$25.00. The law states that authorization must be secured from the employer or the Commissioner. The Commissioner is only put in there so that if you are refused authorization, the Commissioner might be called upon. Therefore, the authorization of their services should be secured from the employer or insurance company, but that is all; they have nothing to say about who shall do the operation. They have been doing that in New York and it is illegal. They have a right to send a medical inspector to agree that the operation is necessary.

In response to questions, it was stated that authorization for special services need not be in writing although it is to be preferred; that hospitals may not operate a medical bureau for the care of compensation cases; the City of New York must secure a license for its clinics; the attending physician must be the judge as to when emergency treatment ceases.

At Dr. Podvin's request, Mr. Michael Murphy, Acting Director of the Compensation Division in the Department of Labor, was introduced. He emphasized the importance of the physician reporting within the 48-hour period his acceptance of a compensation case; urged that the report contain a detailed statement of the case, and recommended that it be notarized so that in the event, if later there should be trouble, the report can be used as a legal document. In the event that cases are transferred, the physician receiving the case should make a report upon it as he would of any other new case coming to him, and this in spite of the fact that he should receive from the preceding physician a complete statement of his findings and what he had done. He stressed the importance of sending to the Division of Workmen's Compensation in the district, carbon copies of all reports that are submitted to the employer and to the insurance carrier. He urged the physicians to submit promptly, conscientious estimates of the period of disability. The difficulty of making an accurate estimate is recognized, but if the period must be extended there is no prejudice to the case, while if the period is not mentioned a very definite prejudice may arise.

After luncheon Dr. Irving introduced Dr. Sondern, President of the State Society, who said in part:

I am very glad to be present today and I feel that the secretaryship is the most important job in a County Society. As to the matter of workmen's compensation, this law was framed and the medical profession was given its first

opportunity to administer a law that had to do with itself. If the public realizes we are doing this job well, then in the future any job that has to do with the medical profession will fall into our hands. Relative to the pneumonia matter and the venereal disease matter, much could be said about both, but in your consideration of it I would like to say that at the recent meeting in Saratoga of the public health officers of the State, I took the liberty of making a statement that I would like to impress on you. We must, whenever opportunity presents, make clear to the people of the State that we are in favor of everything that is done for the good of the people and the good of the State by the public health authorities, just so long and just so far that they play fair with the profession. I called attention at that time to the function of the public health authorities on the one hand and the medical profession on the other. All environmental procedures, everything that has to do with public health that the public health authorities should do—if it is within their sphere, we should help them. Every facility that they can get from progress in the science of medicine should be made available to every sick person and to every physician who takes care of such sick person. But the care of the individual that is sick, the protection of his health when he is not sick, is a personal service and that personal service is the prerogative of the practicing physician and a thing with which the public health authority has absolutely nothing to do. It is the duty of the public health authority to see that the profession as such does its job properly. If we don't treat syphilis or pneumonia as we should treat them, then you can not blame the public health authority, in the interest of public health for taking your place. But so long as you do your duty so long as you are modern, so long as you take care of these people in a personal capacity it is your service and not a public health service. The public health duties must be to develop the environmental service to the best of its ability. It is your duty to keep modern in touch with every development so that you may be able to use the facilities that are put at your command and not to give the public health authorities the opportunity to say that you are not doing what you should in the light of present medical knowledge. I think we are all awakening to this fact, also the public health authorities are awakening to a little sharper line between their duties and ours. All of us that have to do with organized medicine in any way are proud of our men and of their progress. I can assure you that in the short time I have had the privilege and honor of being your executive officer, what I see makes me feel that it is a thing to be proud of.

In closing his remarks of the morning, Dr. Podvin suggested that the following procedure be used in selecting arbitration boards. That instead of the president of the County Society naming two persons, he submit a list of ten or twelve names to the Commissioner of Labor with the request that he make a selection from that list.

Dr. Aranow, Chairman of the Committee on Legislation, was introduced and offered the following recommendations. That only men with political sense or experience be appointed members of the County Legislative Committees, that close relationship be established with political leaders and legislators, that the committees endeavor to enlist the interest of local humane societies in attacking anti vivisection bills, that the committees should prepare themselves to combat abuses that may arise in the administration of the new Workmen's Compensation Law, in opposing any new chiropractic bill, in overcoming the legal objections to our physicians' lien bill, in ascertaining the reaction of physicians in the Society to nurse anesthetists, and to dispensary abuses.

Dr. Elliott, Chairman of the Committee on Economics, said there are three economic issues squarely confronting the physicians. First encroachment on the field of the private physicians by the hospitals, second, contract medical practice and, third, compulsory health insurance. With regard to the first he felt that the Society has a duty to see that legal objection to the practice of medicine by a corporate body be made definite, to the second he stated that in New York City a large business concern, within the last two months decided on a pay-roll deduction of from 12c to 32c a week and with this amount were employing physicians on contract to render services to the employees. He warned the secretaries that the Federal Government has not abandoned its objective of compulsory health insurance.

Dr. Prudhon, Secretary of the Jefferson County Society, called attention to the lack of regulation over medical activities in small rural hospitals and convalescent homes. After hearing his discussion the Conference adopted the following resolution:

Resolved that it is the feeling of the Secretaries' Conference that the establishment of standards of small community hospitals and nursing homes be studied by the Public Relations Committee of the State Society.

Dr. Odell, Secretary of the Schoharie County Society, suggested that County Societies having good programs might invite neighboring County Societies to their meetings, or might report to secretaries of neighboring Societies the good features of their programs.

In response to a request that there be a "clearing house" on programs, Dr. Lawrence said that the Albany office is maintaining a file of that character at present. Its sources of information are almost entirely the newspapers, and he asked that

the Secretaries cooperate with him in developing that file.

Dr. Garen, Secretary of the Cattaraugus County Society, gave a very illuminating report on the number of physicians in his county receiving some income from governmental sources. The Conference thought the Economics Committee might make a similar study of every county. Dr. Elliott responded that Dr. Garen is a member of his Economics Committee and this was a partial report on a subcommittee's activities.

Dr. H. Jackson Davis, having been invited to confirm what was stated with regard to the policy to be pursued in securing medical care for persons engaged under the WPA, made such confirmation and stated further that at present employees on the WPA are expected to pay for such medical

services as they and their families may need, from their earnings, and not to expect supplementary relief; but, in his opinion, the policy will likely be changed because the wages are too inadequate to cover all the workers' financial obligations including medical care. He forecast that complaints over disputed bills and other debatable matter will be more promptly handled as the machinery of the new regime becomes established. He stated that the WPA is prepared to adopt the programs for providing medical care as rapidly as the Workmen's Compensation Committee develops them.

There being no other questions or matters to be discussed, and the hour of 3:45 P.M. having arrived, the Conference adjourned.

JOSEPH S. LAWRENCE, M.D.,
Executive Officer.

AMONG OTHER THINGS

The Arizona legislature has passed, and the Governor has signed, an act to license naturopaths to practice in that state. The Governor, Dr. Moeur, is a physician. Says *Southwestern Medicine*, organ of the state medical association: "How a Governor who had made an honorable living in the life-long practice of medicine could fail to veto this pernicious menace to the public health when it came before him, is more than we can understand."

Mike, badly injured in an accident, was rushed to a hospital where his wife soon followed. A surgeon went to the ward with her. At the door he saw a sheet was over the patient and said to her, "Madam, your husband is dead."

A voice from under the sheet said: "Naw, I'm not."

The wife replied, "Hush, Mike, the doctor knows best."

—*Wall Street Journal*.

The following laughs are by-products of cross-examination of witnesses before the Industrial Commission of Colorado. They have been collected by J. C. Peters, court reporter, and they are furnished to *Colorado Medicine* by request.

Question. Do you think you would be better off with that finger amputated?

Answer. Well, I don't know; I never had it off.

* * *

Q. Is your husband living? A. No.

Q. Is he dead? A. Yes.

Q. How many children have you? A. Five.

Q. How many are boys? A. Three.

Q. Are the other two girls?

* * *

Q. Are you getting any better as time goes on?

A. No, I don't think I am. I think my weakness is getting stronger.

Health was advertised in a big way at the Rochester Exposition in September by exhibits prepared by committees of the County Medical Society and other health bodies. The committee on the care of eye defects, collaborating with other organizations, had a booth displaying aids to vision and giving information on saving sight. Tests were given, illustrations of eye hazards shown, and symptoms of defective vision described.

Another committee joined with representatives of the Tuberculosis Association and the Bureau of Milk Publicity in a display urging the drinking of more milk. Another exhibit showed modern ways to fight tuberculosis. Aids to physicians and nurses, including the x-ray, the tuberculin skin test, the pneumothorax treatment of the lungs and sputum analysis were demonstrated. The exhibit was sponsored by the Tuberculosis Subcommittee of the County Medical Society.

The Monroe County Society for the Handicapped had an exhibit showing how to help crippled children, including the hard of hearing and those whose sight is imperfect. The society has been far reaching and this past year had a case at Warm Springs Foundation, a case at the Reconstruction Home at Ithaca, a case at General Hospital, besides other cases in their homes.

County Societies

Albany County

Practical application of the "Detroit Plan" in Albany County raised, in 1934, the number of children under 5 years of age immunized against diphtheria from 32 per cent to 54 per cent.

Because of its value as a model of county society action, the report of the Public Health Committee is reproduced here in full detail.

DIPHTHERIA PREVENTION

REPORT OF THE PUBLIC HEALTH COMMITTEE
of the
ALBANY COUNTY MEDICAL SOCIETY
on the

PARTICIPATION PLAN IN PREVENTIVE MEDICINE

For several years there has been a feeling in the Albany County Medical Society that physicians should take a more active interest in preventive medical procedures and include them as a part of their regular office practice. One of the simplest and at the same time the most important of these preventive procedures is diphtheria prevention.

Your Public Health Committee has been studying and considering means of encouraging the members of this medical society to take an active interest in and to participate in preventive medical measures on a city-wide scale that would establish their offices in the minds of the people, as the place where preventive medical services are available.

The Albany City Department of Health and the Albany Board of Education had previously been carrying out diphtheria prevention inoculation in the city hall and in the public schools. Representatives of these two official agencies met with the Public Health Committee and plans were formulated that met the hearty approval of each group.

Dr. Henry F. Vaughan, Commissioner of Health, Detroit, Mich., came to Albany twice and outlined the Medical Participation Plan that has worked so successfully in Detroit. At these visits, meetings were held with the Mayor and his cabinet, small meetings with the representatives of the City Department of Health and the Board of Education and large meetings of the whole County Medical Society and other interested persons.

The Participation Plan for Diphtheria Prevention as finally evolved and found suitable to all agencies involved, is prac-

tically the Detroit Plan with such modifications as would more successfully meet the conditions existing locally. This plan was approved on its general outline by the State Medical Society at its meeting in New York City in May 1933, and by the Albany County Medical Society on June 27, 1934.

ESSENTIALS OF THE PLAN

1. The Public Health Committee of the County Medical Society, of which the local health officer is a member, acts as the planning board.
2. Committee meetings are held one each week throughout the year, except during the months of July and August.
3. A printed statement of the plan to be proposed at the regular meeting of the County Medical Society is mailed to each member one week before the meeting at which it is to be considered.
4. All plans are developed within the Committee and approved by County Medical Society at a regular meeting before being announced to the public.

To include the city health officer, the chief school medical inspector and other representative of the official health agencies is considered necessary to the success of the plan.

Weekly meetings have been found necessary if well thought out programs are to be presented to the society. The presentation of immature, impolitic or impractical plans to a group the size of the county medical society definitely retard the progress of any sound program.

It is deemed important that each member is fully informed on all proposals before the meeting is held. This provides the membership of the society with time to consider each step carefully.

No plans are released to the press, except after they have been approved by the society as a whole.

THE PROCEDURE

1. The form of agreement that the P. H. Committee proposed to the County Medical Society and found acceptable to the medical profession, to the city health department and to the school officials, will be found at the end of this article (See Appendix A)
2. After this was adopted as a working plan, a printed letter was sent to each member of the county Medical Society giving details of the working program. (See Appendix B)
3. With this was sent a post card with the return address of the Public Health Committee. On this card the physician designated the days and hours that he would be in his office ready

to do this special piece of preventive medical work. (See Appendix C)

4. The names of the physicians who signed and returned these cards were printed in alphabetical order and used as a part of the educational work. (See Appendix D)

5. As a part of the educational work of the campaign, a letter "To the Parents" was printed and distributed by the public health nurses, school nurses, and others as described under "Nurses." (See Appendix E)

THE WORK

A. The active propaganda work was done largely through the City Department of Health and through the city schools; precedent for the medical profession remaining in the background in this field is traditional.

1. Some item of interest and importance appeared in each newspaper every day. Pictures were found especially helpful.

2. Talking moving pictures films were furnished to each theatre. These were supplied by the Metropolitan Life Insurance Co. and the State Department of Health free of charge.

3. A ten or twenty minute discussion of diphtheria prevention was given at each school in the public and the parochial systems. This was continued until every child had heard at least one of these talks.

Particular stress was placed on the importance of diphtheria immunization in the preschool group. Pupils with preschool brothers and sisters were asked to take the sheet "To the Parents" to their homes and explain the matter to their elders. Many parents commented on how their children succeeded in convincing them.

B. The Public Health Nursing service is a highly essential part of this plan. Attention is directed to the statistics showing the amount of nurses' services needed and used in this campaign.

The committee would not expect a successful outcome, if the amount of the public health nursing service was below that available in this campaign.

While general educational work is necessary to move the mass of the people, the direct individual appeal of having a trained public health nurse ring the door bell and present the subject properly is the one that gets the best results.

Lists of the names and addresses of children 5 years of age were obtained from the annual school census and from the birth certificates of the local department of health.

The births of the past five years were put on a spotmap and the city divided into districts, so that each district would have about the same number of children. The nurses then started making house to house calls and each evening reported the names on their list that they had seen that day.

C. The cooperating physicians were in their offices at the hours they had chosen ready with equipment and fresh toxoid to render the service.

THE RESULTS

The estimated population of children under 5 years of age in Albany in 1934 is 8,591, and the number of births was 2,343 for the year 1933.

The estimated population of children from 5 to 9 years of age was 8,202. This is the number found by the school census enumerators.

Prior to this year's campaign 2,745 children under 5 years of age had been reported as having received complete inoculation against diphtheria. Every day the nurses reported a number of children whose parents said they had been inoculated in previous years. Inasmuch as the physician had not reported these inoculations, no record was made of these reports.

During the campaign 1,884 children under 5 years of age were given complete immunizing treatment. There were 153 more who took the first dose but did not return for the second dose of toxoid.

There can be no doubt that the two dose immunization with toxoid made the number of incomplete treatments much smaller than would have been the case if a three dose technic had been used.

It is hoped that during the Diphtheria Campaign of 1935, a one dose technic will be available which will eliminate even the small loss that has occurred this year.

The addition of 1,884 children under 5 years of age to the 2,745 children of this age group immunized in previous years, makes a total of 4,629 of a possible 8,581 or 54 per cent.

In estimating the number of children immunized under 5 years of age, it must always be remembered that the immunized five year olds leave this group each year and their places are taken by the number of persons born later, who are all susceptible to diphtheria as soon as they are six months of age.

Special effort was made in this campaign to reach the preschool children.

There were, however, 280 children aged 5 to 9 years completely inoculated during the campaign. These added to the 3,791 previously immunized means that 4,071 of these children have been immunized or 49 per cent.

The volume of nursing work used to accomplish this result is represented by 320 "nurse days." The public health nursing staff for this campaign was made up of the T.E.R.A. nurses from the city department

of health and the City Welfare Department, Albany Guild for Public Health Nursing, Veterans' Bureau, and the New York State Department of Health. The direct supervision of this entire group of nurses for the purposes of this campaign was the responsibility of the City Department of Health.

"Three hundred twenty nurse days" is the equivalent of the services of 32 nurses for a ten day period. This amount of service was used to raise the immunized population under 5 years of age from 32 per cent which it was at the beginning of the campaign to 54 per cent which it was at the close. This means that there was actually accomplished six or seven complete inoculations for each nurse's day's work.

THE ECONOMIES

As noted in Appendix A, paragraph 10, the City Department of Health paid the cooperating physicians for all cases unable to pay for themselves. Your committee feels that the family physician knows and can determine who is unable to pay much better than anyone not involved in rendering the service.

It was reported to be the experience of several physicians, that certain families in their practice would take their children to a free clinic, but when they took the children to their own family physician's office, —they paid for the service.

Due to the stringent financial situation, some interested parties feared that the cost to the city would be so great that the Participation Plan would fail.

The communication "To the Parents" (Appendix E) clearly states "A fee of \$1.00 for each inoculation has been agreed upon. Because this is approximately one-third the usual fee charges for such service, it must be paid at the time of each visit."

Twenty-one per cent of the 2,164 were paid for by the parents at the time of the service rendered.

The total cost to the city for all items including physicians, printing, carfare, stationery, etc., was \$2,637.10, and the net result is that there were 2,164 more children immunized than before the campaign was begun.

The year preceding this campaign, diphtheria occurred in one of the city hospitals in epidemic form. Before this epidemic was stopped the City, the Welfare Dept. and the T.E.R.A. spent \$2,197 on the nurses, care of indigents, and the cleaning and renovating. The cost of the entire participation plan of diphtheria prevention was only slightly more than the cost of curbing this one hospital outbreak.

SUMMARY

The city has 2,164 more children immunized against diphtheria at a cost of \$2,627.10, or slightly more than one dollar each. Fifty-four per cent of the children under 5 years of age and 49 per cent of children 5 to 9 years of age puts Albany in a very select group of American cities in regard to this important measure.

The parents have satisfaction of knowing that they can have their children immunized against diphtheria without question of their ability to pay. The work is done in the office of their family physicians, where they should go for all preventive as well as curative medical services.

The physicians have performed public service by making it possible for all of the children in the families under their care to have this protection. Parents are deflected from the "free clinic" and directed to their family physicians, their logical health advisors. Also, the physicians have received a fee (reduced) for the inoculation of 2,164 children many of whom would otherwise have gone to the "free clinics" or received no attention in diphtheria prevention.

In general, mutual respect engendered by this group of physicians representing organized medicine, the city health department and the city schools, sitting together to work out serious public health problems has been most stimulating.

Your committee is convinced that no one of these three groups could have worked out a program by themselves that would have been as advantageous to all concerned as that which has evolved by the Participation Program.

Appendix A

MEDICAL SOCIETY OF THE COUNTY OF ALBANY

PUBLIC HEALTH COMMITTEE

The Committee will present for discussion and action at the meeting June 27th, the following program:

1. That the Society, with the cooperation of the Health and Education Departments of the City, undertake a campaign of diphtheria prevention;
2. That this campaign be in October and November, 1934, and that the first inoculation be given only during the last week of October and the second, only during the last week in November;
3. That toxoid alone be used and furnished by the Health Department;
4. That the campaign be limited to infants and children 10 years and under;
5. That the fee for each inoculation, during these two weeks only be \$1.00.
6. That those physicians desiring to cooperate in this campaign sign an agreement with the

Society, specifying days and hours, during these two weeks, when they will inoculate at these rates; that they will attend a symposium in October on diphtheria; and that they report to the Health Department the name of each child so inoculated;

7. That the Education Department for the school year 1934-1935 will not hold diphtheria clinics in the public schools; nor the Health Department hold such clinics in the parochial schools;

8. That the Health Department agree:

- (a). Not to administer diphtheria toxoid in the health office or elsewhere during October and November, 1934.
- (b). To reimburse cooperating physicians at the above agreed fee schedule for every indigent case inoculated and reported to the Health Office.
- (c). To send in May, 1935, to parents of children, inoculated in this campaign a letter urging them to report back to their physician for a Schick Test, and the day and hours when each cooperating physician will be prepared to render this service.

9. That the fees charged for these Schick Tests be \$1.00 for the test and \$1.00 for the reading.

10. That the Health Department reimburse cooperating physicians as per this fee schedule for those unable to pay, and reported to the Health Department.

Appendix B

MEDICAL SOCIETY OF THE COUNTY OF ALBANY
DEPARTMENT OF HEALTH OF THE CITY OF ALBANY
DEPARTMENT OF EDUCATION OF THE CITY OF ALBANY

DEAR DOCTOR:

The Medical Society has adopted the following program for a campaign of diphtheria prevention:

1. That the Society, with the cooperation of the Health and Education Departments of the City, undertake a campaign of diphtheria prevention;
2. That this campaign be in November and December, 1934, and that the first inoculation be given only during the first week of November and the second, only during the first week in December;
3. That toxoid alone be used and furnished by the State Health Department through the City Health Department;
4. That the campaign be limited to infants and children between six months and seven years of age;
5. That the fee for each inoculation, during these two weeks only be \$1.00;
6. That those physicians desiring to cooperate in this campaign sign an agreement with the Society, specifying days and hours, during these two weeks, when they will inoculate at these rates; that they will attend a symposium in November on diphtheria; and that they report to the Health Department the name of each child so inoculated, both private and public cases;
7. That the City Education Department for the school year 1934-1935 will not hold diphtheria clinics in the public schools; nor the Health Department hold such clinics in the parochial schools;

8. That the City Health Department agree:

- a. Not to administer diphtheria toxoid in the health office or elsewhere during November and December, 1934;
- b. To reimburse cooperating physicians at the above agreed fee schedule for every indigent case inoculated and reported to the Health Office.

Five years experience in Detroit has demonstrated that preventive medicine conducted by the family physicians in their own offices, collaborating whole heartedly with the health and education department has resulted in:

1. Larger percentage of children protected against diphtheria;
2. Resulting drop in the incidence of the disease;
3. Marked reduction in total diphtheria cost to the municipality;
4. Increased income to cooperating physicians;
5. Eventual abolition of free diphtheria prevention clinics.

Such results are possible, however, only if the great body of family physicians participate actively by joining the list of cooperating physicians. This cooperation will make it possible for every child to go to his own doctor for inoculations.

Parents of infants and children between the ages of six months and seven years will receive: a "Notice to Parents" telling of the purpose of this campaign, a list of cooperating physicians with their addresses and the specific days and hours set aside by each for this purpose, and the cash fee schedule set by the Society. They will be urged to consult their own family physician if on this list, otherwise the nearest cooperating physician.

The fee schedule adopted applied only to those who report at your office on the days and during the hours specified by you on the enclosed card. Those applying at any other time may be charged your usual fee.

Cooperating physicians agree to attend one meeting on diphtheria. This will be held on Friday, November 2nd at 5 P.M. sharp at the Fort Orange Post, New Scotland Avenue. Doctors Charles K. Winne and Otto A. Faust will speak. Fresh toxoid and literature will be distributed and all questions pertaining to details of the campaign will be answered.

The future course of preventive medicine in Albany County is in our hands. We can retain it only if we demonstrate our unity and our leadership. Do your share by signing now the enclosed post card and mailing it. These cards must be received by Monday, October 12th.

Signed,

ARTHUR M. DICKINSON, M.D.
FRANCIS W. DODGE, M.D.
EDWARD S. GOODWIN, M.D.
DON M. GRISWOLD, M.D.
ALFRED L. MADDEN, M.D.
OTTO A. FAUST, M.D., *Chairman*
Committee on Public Health

October 8, 1934.

Appendix C

I agree to cooperate with the Medical Society of the County of Albany in the campaign of diphtheria prevention.

I consent to the inclusion of my name on a list of physicians who desire to cooperate in this work and agree to attend one clinical conference on this subject. I will set aside the following time during the weeks

of November 4 to 10 and December 2 to 8, 1934
 Monday Tuesday Wednesday Thursday Friday Saturday
 Hours from _____ to _____ M D

(Signed) _____
 Office Address _____

Appendix D

This contained the names, addresses and hours for immunization of 90 cooperating physicians, representing practically all men who are not in specialties industrial or state work.

Appendix E

TO THE PARENTS

During the months of November and December, 1934 the Departments of Health and Education of the City of Albany and the Medical Society of the County of Albany are cooperating in an effort to protect against diphtheria all children of Albany between the ages of six months and seven years.

The members of the Medical Society of the County of Albany have agreed to give the necessary two injections of toxoid in their offices at a minimal fee during the first full week of November and December, 1934. A fee of \$1.00 for each inoculation has been agreed on. Because this is approximately one third the usual charge for such service it must be paid at the time of each visit. If you are unable to afford this fee, the Health Department of the City of Albany has agreed to pay your doctor for this service.

In order that your physician may know when you will bring your child to his office for these inoculations we request that you fill in the attached appointment slip.

Erie County

NEW REGULATIONS for medical care under the Emergency Relief Bureau of Erie County are expected to iron out some of the difficulties that have been hampering the work.

Heretofore County Emergency Relief Bureau investigators have had authority to direct the disposition of county clients needing medical care. In the future, however, the sole responsibility for the disposition of medical clients will rest with the medical supervisor of each county home relief district.

District medical supervisors in turn are under the direct supervision of the chief medical supervisor, who has issued orders which will centralize responsibility in the equitable distribution of County medical home relief.

Clients receiving medical aid from the ERB of Erie County will have the opportunity of retaining their family physician and clients having no family physician will be supplied with one chosen—alphabetically arranged and in rotation from an approved list of physicians in that district—by the District Medical Supervisor.

In a cooperative effort to solve the difficult problem of the many long drawn-out chronic medical cases receiving welfare aid from the County Emergency Relief Bureau, President Bauckus, and the Comitia Minora of the Society have agreed to appoint consultants from the membership of the Society to confer with the family physician on the future care and disposition of such cases when the Emergency Relief Bureau of Erie County so desires.

Additional evidence of cooperation lies in the fact that the Comitia Minora of the Society has agreed to act in an advisory capacity to the medical administration of the Emergency Relief Bureau, but will act also as a court of appeals, and when necessary will function as a disciplinary committee in dealing with any unethical practices of physicians taking care of clients who are obtaining aid from the Emergency Relief Bureau of Erie County.

Attention again is called to the importance of receiving proper authorization from the District Medical Supervisor if the physician expects to be reimbursed by the Administration of the Emergency Relief Bureau of Erie County. In case of an emergency call, the physician must request authorization within 48 hours.

Monroe County

TUBERCULOSIS is slowly decreasing in frequency in Monroe County, according to a report of the Tuberculosis subcommittee of the Medical Society of the County of Monroe.

The report is based on a study of the deaths resulting from the disease in the county during the last six years, and was made by a committee headed by Dr. John T. Lloyd. The conclusion is contrary to that reported recently in a study made by the New York Tuberculosis and Health Association.

"Tuberculosis in Monroe County is decreasing, not increasing," the report reads. "This conclusion is inevitable when long range mortality rates are studied and is diametrically opposed to the idea created recently by published mortality figures for Rochester. In July, a New York dispatch stated that a survey made by Godias J. Drolet, statistician for the New York Tuberculosis and Health Association, showed that despite a national drop of 4 per cent in tuberculosis deaths, Rochester's 1934 mortality rate for this disease showed an 18 per cent increase over 1933 figures."

The report of the Monroe County society points out that while the New York man's figures may be correct, they do not give the correct impression as a single year's figures do not indicate a trend and for any indica-

tion of significance figures should not be used for less than a five-year period.

"The 1934 increase was due to a sharp, unusual drop in the number of deaths from the disease in 1933 and a return to the normal rate of decline in 1934," the report says.

Other members of the committee in addition to Dr. Lloyd include Dr. Ezra Bridge, Dr. S. H. Erlenback, A. M. Johnson, A. D. Kaiser, C. G. Parnall, E. K. Richard, W. A. Sawyer and E. G. Whipple.

New York County

THE MEDICAL COMMITTEE for the Defense of Ethiopia, comprising thirty colored physicians, dentists, pharmacists, nurses and technicians, announce an "energetic drive to send immediate medical assistance to the Ethiopian people." The group was organized before Ethiopia made its appeal for aid, it was pointed out by Dr. Arnold Donawa, secretary of the committee, in a statement from 2,384 Seventh Avenue. Dr. J. J. Jones of 151 West 140th St. is chairman.

The committee plans to appeal to wholesale concerns and to the public for medical supplies to be forwarded to Ethiopia.

DR. CHARLES NORRIS, chief medical examiner of New York City since 1918, died suddenly at his home on September 11. He was 67.

Queens County

THE OPENING of the Queens General Hospital in Jamaica was postponed from October 1 to October 30.

Dedicatory exercises will be held on the opening date, and during the remainder of the week, from Wednesday, October 30, through Saturday, November 2, the institution will be open for public inspection.

Actual service will be built up progressively. Members of the visiting medical and surgical staffs assigned to service in the out-patient department will be notified to report for duty on November 6, and it is planned to admit the first ward patient about November 18.

DR. CARL HUNT, a practising physician of Queens and formerly identified with the Lee Shubert theatrical enterprises as casting director and adviser, has filed suit for \$100,000 against Joseph Vernon Reed, theatrical producer, claiming he was libeled in the latter's book, "The Curtain Falls," published in 1934.

Dr. Hunt alleges that in the Reed book he was referred to as a former "horse

doctor" and "a sycophant," and that as a result of the publication he lost his job with Lee Shubert and his reputation as a doctor was damaged.

Rensselaer County

THE GENIALITY AND WARM FRIENDSHIP shown by Dr. David W. Houston, Sr., to all and sundry on the streets of Troy bring this fine tribute from the Troy *Record* on the day after his death on September 11 at the age of 78:

"Such people as Dr. Houston are a heaven to any community. They clear the atmosphere; they keep a city sweet. They offer the blessing of benignity to a materialistic age. They are not always assessed at their true value while they live; but when they pass out of the life of their town suddenly their old associates realize what such cordiality was worth and how much they have lost."

Rockland County

A MODERN \$500,000 TUBERCULOSIS HOSPITAL, with the most efficient equipment, shortly may be built in Rockland County.

Plans for such a sanitarium to be erected at Summit Park in place of the institution declared inadequate and outmoded by Dr. William J. Ryan, its superintendent, have been passed unanimously by the County Board of Supervisors.

In order to take advantage of Federal aid which soon may be withdrawn, the plans will at once be submitted to Washington and, if approved, it is expected a grant of \$204,592—about half the cost of building and equipment—will be available under PWA.

The remainder, estimated at approximately \$250,057, would be borrowed by the county probably by bond issue at the discretion of the Supervisors.

The present capacity of the institution is 46 beds, whereas, during the past seven or eight years, the hospital has had a daily average of about 52 patients and a waiting list.

The present sanitarium is a frame building and is very combustible.

Westchester County

PLANS HAVE BEEN COMPLETED for the construction of two new floors on the central building of St. John's Riverside Hospital in Yonkers at a cost of about \$25,000. This construction will provide 5,500 square feet of additional floor space allowing for 30 new beds to be devoted to medical cases. There will also be space for two solaria for semi-private cases.

Practice of Pharmacy by Aliens

A few months ago an interesting case* involving the practice of pharmacy came before an Appellate Court in one of the Pacific Coast States.

Certain Japanese who were desirous of becoming licensed pharmacists had been denied the privilege of taking the examinations to qualify as such on the grounds that they were not citizens of the United States. There was no doubt of the fact that the applicants were not such citizens, and that they were ineligible to become such citizens. The State statute regulating the practice of pharmacy forbids the registration of any persons not citizens of the United States regardless of their education, training, ability, character or the like.

The Japanese thereupon petitioned for a writ of mandamus to direct the State Board of Pharmacy to permit them to take the examination. Their application was denied, and the petitioners took an appeal to the District Court of Appeals, which directed that the ruling of the lower Court should stand.

The chief point urged on behalf of the petitioners before the Appellate Court was that the provisions of the Pharmacy Act, which had been invoked against them, were in conflict with the Treaty of Commerce and Navigation between this country and Japan, and hence were invalid. The said Treaty contained the following provisions:

"The citizens or subjects of each of the High Contracting Parties shall have liberty . . . to carry on trade, wholesale and retail, to own, . . . shops . . . and generally to do anything incident to or necessary for trade upon the same terms as native citizens or subjects, submitting themselves to the laws and regulations there established.

The Court determined that under the terms of the treaty, the whole question came down to one of whether pharmacy is a profession or a trade. The decision was that pharmacy is a profession and that for that reason the treaty had not been violated. In so deciding the Court distinguished between pharmacy as a profession, and the business of owning and operating a drug

store. The latter, the Court indicated, a Japanese could, under the State and Federal Laws, engage in. The Court said in the opinion:

The whole matter resolves itself down to the question: Is the occupation of being a pharmacist a trade or is it a profession? If the practice of pharmacy is a trade, the treaty is violated, if it is a profession the treaty is not violated. In this connection we must keep in mind the distinction between the business or trade of a druggist as the owner or operator of a drug store and the practice of pharmacy as such. A pharmacist may compound prescriptions. While he is so doing, he is exercising his knowledge of the science of pharmacy in compounding drugs; thereafter he or someone else may sell the medicine to a customer. If he does so, he becomes, in the doing of said act, a clerk or merchant. The statute which is under discussion does not prevent aliens from operating or owning drug stores or working as clerks therein; it merely prohibits them from being registered as pharmacists and from acting as such. Webster's New International Dictionary in defining the word "trade" says: "The business which a person has learned, and which he engages in, for procuring subsistence, or for profit; occupation; esp., mechanical employment as distinguished from the liberal arts, the learned professions and agriculture: as, we speak of the trade of a smith, of a carpenter, or mason, but not now of the trade of a farmer, or a lawyer, or a physician." In defining the word "profession" the same authority says: "That of which one professes knowledge; the occupation, if not purely commercial, mechanical, agricultural, or the like to which one devotes one's self; a calling in which one professes to have acquired some special knowledge used by way either of instructing, guiding or advising others or of serving them in some art; calling; vocation; employment, as the profession of arms; the profession of chemist." We are satisfied that the practice of pharmacy is a profession, and that the Pharmacy Act is not in violation of the referred to treaty.

The second argument urged by the appellants before the Court was that the provisions of the Pharmacy Act complained against, constituted an abuse of the police power, creating an arbitrary and improper classification against aliens, thereby denying to them the equal protection of the laws. That argument likewise was rejected, the Appellate Court saying:

* Sashihara v. State Board of Pharmacy, 46 Pac. (2nd) 804.

We are satisfied also that the object sought to be accomplished by the legislation in question is the protection of the public health, safety and general welfare, and that there is a reasonable relation between that object and the means adopted. This court cannot say that the classification excluding aliens is "palpably arbitrary." In the practice of pharmacy, chemicals and poisons are constantly used and compounded. If not handled with great caution, much harm might be inflicted. And it is obvious from these facts and others that there may be a reasonable basis for the existence of the discrimination against aliens, and therefore that the act under discussion is not an abuse of the police power. Neither do said sections deny to aliens the equal protection of the laws.

In connection with the foregoing case it is interesting to note the similarity between the statute under scrutiny, and the provisions of the New York Education Law regulating the practice of medicine. One of the provisions of section 1256 of that Law, which is the section regulating the admission of candidates for examination, requires that every candidate must submit under oath evidence that he is a citizen of the United States or has declared his intention of becoming such citizen.

Wrongful Death Action

A physician engaged in general practice, but doing considerable surgery, was called to the home of a boy of about 3½ years old, where he found the child suffering from a fever and cough and complaining of pain in the right shoulder.

He examined the child and concluded that he was suffering from bronchitis and possible fracture of the right clavicle, although there was no history of a fall causing such an injury. The doctor's impression was that there was some crepitus at the outer end of the right clavicle with dropping of the level of the right shoulder. There was, however, no swelling or redness in the region of the right shoulder at that time.

He examined the child's throat and ear drums and found them negative. He applied a sling for the right arm and prescribed a cough mixture. Examination of the child was difficult as he was not well developed mentally for his age and resisted the doctor's every effort to examine him.

The doctor kept in touch with the case for about a week by telephone, and apparently the child was getting along well. At the end of that time he called to see the child and found that the arm was still in the splint. The child continued to have fever but there was no evidence of infection.

Several days later the doctor again saw the child and there was no material change in his condition. A few days thereafter, another doctor was called in the case and he removed the child to a hospital where the first doctor saw him in consultation with other doctors.

While at the hospital, the child ran a very high temperature and died from a general streptococcus infection in about ten days.

An action was brought against the defendant by an administrator who was appointed for the child, in which the claim was made that the defendant doctor had negligently caused the death of the infant in failing to properly diagnose his condition.

Just as the case was about to be reached for trial the plaintiff's attorney, finding that he could obtain no offer of settlement from the doctor, consented to discontinue the action thereby acknowledging that he was unable to prove his cause of action.

Removal of Metallic Fragment from Finger

A young girl came to the office of a general practitioner and told him that she had broken off a piece of needle in her left index finger while operating a sewing machine. She had been referred to him for treatment by her employer. The doctor thereupon took an x-ray picture of the finger, and a foreign body approximately ¼" in length was shown near the tip of the terminal phalanx of the index finger. Adjacent thereto, and lying in the soft tissues, was shown a tiny particle of metal so small that it could scarcely be measured. The doctor made an incision in the finger and readily removed the larger particle. He decided against trying to find the tiny particle, believing that it would do no harm if it was permitted to remain where it was, and deciding that it would be extremely difficult to locate. He bandaged the finger and she remained under his care for several weeks for follow-up treatment.

The finger healed entirely, and at the end of that time she had full function and use of the finger and had no complaints.

It appears that about fourteen months later, she consulted another doctor who after taking X-ray pictures, found that the tiny particle was still in the end of the finger and that there was present a necrosis of the bone.

She was referred by said physician to a surgeon who performed two operations upon her, removing the tiny fragment and curetting the bone. It was the opinion of

the said surgeon that there was no connection between the bone injury and the tiny particle of metal which had remained all that time embedded in the soft tissues without causing any pain or suffering.

After the operations, the patient's finger apparently became stiffened and she instituted a malpractice action against the first doctor, charging that by reason of his failure to remove the tiny particle at the time he treated her, she had gone through a great deal of pain and suffering and had been obliged to undergo two operations and

had been caused to have a permanently stiffened finger.

The action came on for trial before a court and jury, and on the trial, two physicians testified that the defendant failed to follow proper and approved practice in his handling of the case. The surgeon who subsequently operated upon the finger, however, supported the defendant.

The issues were submitted to the jury and a verdict was rendered in favor of the defendant, thereby exonerating him of the charges of malpractice.

Across the Desk

THE TITLE OF DOCTOR," which ought to be a name of honor and distinction, has been so abused and abused by every kind of quack and charlatan that one thoughtful medical writer wonders if it is not time for the physicians to do something about it. True it is not possible legally to prevent a doctor of this or a doctor of that from hanging out a sign reading "Dr. John Doe." But something else is possible, and the Editor of the *Rhode Island Medical Journal* has a plan that is at least worth thinking about. He suggests that the real physicians, the true doctors of the healing art, drop the title Dr. from their office signs, and append only the degree M. D. If all physicians do this, the public will be quick to sense the fact that the latter sign proclaims the true man of medicine, and that the riff-raff, the rag-tag and bob-tail of muscle-thumpers and bone-wrenchers are sticking to Dr. because they have no M. D. to display.

It is unfortunate that our language has no other name that goes lightly and readily on the tongue for the man of healing. Germany has *Arzt* and France has *medecin*, but we stick to "doctor," which may mean anything from a theologian to a veterinarian. The word is about 600 years old, and was originally applied to the learned in general such as the early "fathers" of the Christian Church who were all doctors. Since then it has had some pretty rough usage and we even find a ship's cook commonly called doctor. The "doctor-fish" has a sharp spine on his tail, like a surgeon's lancet, which he uses with deadly skill, and the "blue doctor" is an angler's fly. A wide and varied circle to share the title! These and other interesting facts about the physician's cognomen were given in the inaugural address of President Her-

bert R. Hurter of the Liverpool Medical Institution, whose hobby is etymological research.

The medical practitioner was formerly known as a leech, but it happened that a blood sucking animal bore the same name, so the doctors gave it up. They have been called *medics*, *medicos*, *medicians*, *mediciners* and *medicners*, but, as Dr. Hurter slyly remarks, never *medici*. The word surgeon, too, is about six centuries old, and has been spelled in 30 different ways. That does not include its classical-sounding synonym *chirurgion*, either, which has had 15 different spellings. Any readers who wish to try to make 45 variations on these two words are at liberty to do so. And, after all, it seems that etymologically the word surgeon means simply a handy-man, so there is no need for any of that ilk to feel too high and mighty about it. Our language is ever shifting and changing, ever fluid, never at rest, and it may be that the time is come for the men of medicine to adopt some new title that will distinguish them from the swarm of imitators who curse our land like a plague. The field is open, and the cause is of the best.

MEDICAL MEN who have been visiting Europe are now back with interesting stories to tell, and it is our privilege to share in them. A Detroit doctor had the happy idea of interviewing the common people in various countries to see how they liked their national systems of medical care. He talked freely with the conductors and guards on the trains, the hotel porters, the clerks in the stores, the taxi drivers. He is Dr. Louis J. Gariepy of Detroit, Chairman of the Executive Committee of the

American College of Surgeons for the State of Michigan. To take one interview, he found the conductor and guard on an English train greatly pleased with their panel system. In fact, they had never known any other. Their panel doctor, they declared, was one of the finest in England. Efficient. He had some 2,000 patients on his list, and at his morning consultation he would see 30 of them in 30 minutes! Further questioning revealed the fact that very little examination of the patient took place, if any, and no laboratory tests at all were done. "In every case the patient entered the office with his own diagnosis and received the medicine that he himself prescribed or that was suggested from his description of his symptoms."

To the railroad men that looked like efficiency plus. It certainly was medical rail-roading. But two young surgeons at Saint Thomas Hospital did not share this admiration. They frankly called the panel system vicious. It gave them no incentive to progress, they said, and both were planning to enter the army or navy for their life work after finishing their hospital training. The English doctor gives the patient his bottle of medicine, instead of sending him to the chemist with a prescription, and a recent number of *Punch* pictures a doctor handing the medicine to a rather touseled patient, and asking: "Did the last bottle do you any good?" "Yus," replied the other, "I got sixpence on it." While that is merely humorous, of course, the cold fact is that sick-pay under every health insurance scheme is given on the findings of the panel doctor, and in England the period of hospitalization in surgical cases has doubled since the system was started. That costs millions of sixpences, and somebody has to pay for it. After looking into the medical plans in England, Belgium, Germany, Switzerland, and France, the Detroit doctor loyally comes home with the assertion that the Detroit plan is best, which at least ought to bring a round of applause when he tells the home medical society about his trip.

WEST VIRGINIA'S PRIDE is touched because a Kentucky health bulletin avers that social disease is brought into Kentucky border towns from West Virginia, thus seeming to cast a slight slur on the latter state, as it were. The state medical journal forgivingly says that "we are going to swallow our pride and overlook the incident for the sake of harmony," but it gets back at Kentucky with what is known as

a dirty dig when it remarks airily that "perhaps we have been guilty of carrying germs over the state line and leaving them in Kentucky, but Kentucky should remember that we have yet to complain when they carry Colonel's commissions over our state line and leave them in West Virginia."

A NEW ORGANIZATION in England is named the Smell Society. Part of its work will be to abolish unpleasant odors. Some months ago we suggested that our Anti-noise Society, in abolishing useless noises, should turn their attention to the young Ph.D.'s lecturing around the land in favor of state medicine. Since then all the state legislatures have adjourned without adopting a single one of the bills before them for compulsory health insurance and forcible regimentation of the physicians. This leaves the Ph.D.'s not only in the plight of being useless noises, but also in bad odor, and when the American branch of the Smell Society is organized, there is something ready for the disinfectant. .

THE DOCTOR has surprised everyone by the ready way in which he has turned his attention to economics and politics in the last year or two and has fought off the attacks of the socializers in the states and even in Washington. What other class can show such a clean-cut victory? And it started with almost no preparation, too. Very shortly the legislatures and the Congress will be meeting again, and this time the profession will be in battle array.

Just as an example, let us look at far-off McCook County, in South Dakota. Under the leadership of a physician and a dentist, there has been organized an Allied Professional Group, including all physicians, dentists, pharmacists, nurses, and even the veterinarians of the county. The aims; we are told "are frankly political." All the counties in South Dakota are to be similarly organized, and "political support of candidates will depend primarily upon the candidates' views upon matters affecting professional interests."

The influence of such an organization will be definitely in the public interest, for anything that harms the healing professions harms everybody. No one can assail the medical and health workers for organizing in their own defense. They have been driven to it, and the event will undoubtedly show that, like the Union Army at Gettysburg, they have been "hammered into an impregnable position."

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Commoner Diseases of the Skin. National Medical Monographs. By S. William Becker, M.D. Duodecimo of 283 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

The Medical Man and the Witch During the Renaissance. By Gregory Zilboorg, M.D. Third series, volume 2. Duodecimo of 215 pages, illustrated. Baltimore, The Johns Hopkins Press, 1935. Cloth, \$2.50.

1000 Questions and Answers on T. B. Edited by Fred H. Heise, M.D. Duodecimo of 232 pages. New York, Journal of the Outdoor Life, 1935. Cloth, \$75.

Abnormal Arterial Tension. By Edward J. Stieglitz, M.D. Duodecimo of 261 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

Recent Advances in Diseases of Children. By Wilfred J. Pearson, D.M., M. C. & W. G. Wyllie, M.D. Third edition. Duodecimo of 566 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., 1935. Cloth, \$5.00.

Midwifery. Edited by Sir Comyns Berkeley, J. S. Fairbairn & Clifford White. Fifth edition. Octavo of 740 pages, illustrated.

New York, William Wood & Company, 1935. Cloth, \$6.00.

Obstetrics for the General Practitioner. By J. P. Greenhill, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 304 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

Industrial Medicine. By W. Irving Clark, M.D. & Philip Drinker, S.B. Edited by Morris Fishbein, M.D. Duodecimo of 262 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

The Management of Colitis. By J. Arnold Bagen, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 234 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

Diseases of the Chest. By J. Arthur Myers, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 385 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

Objective and Experimental Psychiatry. By D. Ewen Cameron, M.B. Octavo of 271 pages. New York, The Macmillan Company, 1935. Cloth, \$3.00.

REVIEWED

The Pocket Anatomy. By C. H. Fagge, M.B. Ninth Edition. 16mo. of 333 pages. Baltimore, William Wood & Company, 1933. Cloth, \$2.00.

This book, as its title suggests, is a pocket-size edition, containing 331 pages of anatomy with a complete index. The notable features in this new edition are that the author employs an approved English terminology and presents a comprehensive glossary of changes from the old terminology. The anatomy is presented in an orderly way with concise descriptions.

This book is highly recommended to the student as a complete outline of anatomy, for study and review, and for the practitioner and surgeon, as an aid in reviewing regional anatomy.

JACOB S. BEILY

X-Ray and Radium Injuries. Prevention and Treatment. By Hector A. Colwell, Ph.D., and Sidney Russ, D.Sc. Octavo of 212 pages, illustrated. New York, Oxford University Press, 1934.

This delightful little book is exactly as its title implies—a consideration of the prevention and treatment of x-ray and radium

injuries. It is quite fitting that the first chapter and also the appendix should deal with the matter of protection—protection to the operator and protection to the patient. These sections are especially valuable and had the early workers with the roentgen ray known how to have applied such protection to themselves there would not have been so many disasters.

Beginning with the superficial skin there is full consideration of the early and late changes, the result of irradiation and the care of radiodermatitis. Continuing, not only is the physiological action of irradiation upon various structures and organs of the body discussed but also the deleterious effects which may ensue are fully considered. The recent studies described in this book have caused many of us to change our views in that many structures, such as the heart, liver, and spleen, together with the muscles and nerve tissue, which were formerly considered to be practically immune to irradiation reaction are now shown to be definitely affected by them. It is of interest and importance to know that in treating about the mouth for such conditions as epithelioma, the reaction on the mucosa will be far

greater than that of the skin.

The whole book is a consideration of the physiological effect of x-ray upon the human organism together with the damage that may be produced and the best measures to offset or correct such damage when it has occurred.

Everyone attempting to use irradiation in any form should be thoroughly familiar with the contents of this little volume and it should prove a veritable Bible for him. Your reviewer feels that no one should attempt the use of irradiation in any form without a thorough familiarity with the contents of this book and it should always be within his reach for ready reference.

CHARLES EASTMAN

How to Practice Medicine. By Henry W. Kemp, M.D. Octavo of 158 pages. New York, Paul B. Hoeber, Inc., 1935. Cloth, \$2.50.

This work is intended for medical students and recent graduates. Undertaken after many years of experience in the general practice of medicine, the author gives advice to the young man based on his own seasoned experience.

A volume of this type would fill a useful place in the hospital library as well as in the recent graduate's office.

SAMUEL ZWERLING

Modern Operative Surgery. Edited by G. Grey Turner, F.A.C.S. Second Edition in two volumes. Octavo of 1760 pages, illustrated. Baltimore, William Wood & Co., 1934. Cloth, \$16.00.

This work appears in its second edition. There are a total of 1764 pages, 860 figures, and 11 plates. The binding is attractive and very well done. The paper is of good quality. The print is of necessity small in order to reduce the bulk of the book. It is very clear and easily read. There are 27 contributing authors, each representing his own particular specialty. The subject matter is so inclusive and comprehensive and the number of operations described so numerous that a detailed review is not possible. There is at least one operation for every conceivable surgical condition, including those on eye, ear, brain, plastic surgery, orthopedics, nerves, and so on. In brief, the entire range of modern surgical operations is most carefully and completely surveyed. Only the operations that have proved their value are described. Symptomatology and diagnosis are not discussed. However, the reason for the choice of each operation is given as well as the preparation of the patient, after-treatment, and the difficulties and dangers arising during and after the

operation. The general plan of this edition is the same as the first. New chapters on Radium and Surgery of the Sympathetic Nervous System have been added. All other chapters have been rewritten where operative progress has in any material way made them obsolete since the first printing. For instance, the surgery of varicose veins has been replaced by a description of the injection method. The abdominoperineal excision of the rectum was rewritten by Ernest Miles and brought up to date in every detail.

For a ready and complete reference work on operative surgery, the reviewer recommends this most highly not only to the recent medical graduate but to the active general surgeon as well.

MERRILL N. F. FOOTE

Franklin Paine Mall. The story of a Mind. By Florence Rena Sabin. Octavo of 342 pages, illustrated. Baltimore, Johns Hopkins Press, 1934. Cloth, \$2.75.

Dr. Florence Sabin has written an exceedingly interesting biography of Dr. Mall. Starting with a description of his early childhood on a farm in Belle Plaine, Iowa, the book advances by easy stages to his schooling in a local academy, his later studies in the University of Michigan and his postgraduate work in Leipzig, Germany. It was the influence of a local schoolteacher, a John McCarthy, that revealed the pleasure of study to the youth and launched him on a straight course to a thorough education. In Leipzig, Dr. Mall came under the guiding spirits of Drs. William His and Carl Ludwig, who opened his eyes to the possibilities of original work in the sciences of anatomy and physiology. Dr. Mall's profound reverence and love for Professor Ludwig is tenderly and affectionately expressed in his letters to the latter.

Franklin Paine Mall is little known to the rank and file of the medical profession, and much less known to the general public. Dr. Sabin was one of his pupils and his co-worker for twenty years. The author was very fortunate to come in close contact with the man, for she was able to study at close range his influence upon medical science and education in America. It was through his efforts that the inductive method of teaching was inaugurated in Johns Hopkins and later adopted by all the other medical institutions in this country.

This book, as a whole, can be given the highest praise. It should prove of especial interest to graduates of Johns Hopkins University.

WILLIAM RACHLIN

Symposium on Surgery of the Chest

ACUTE EMPYEMA OF THE PLEURA

HOWARD LILIENTHAL, M.D., F.A.C.S., *New York City*

Surgeons who do most of their work in diseases of the chest—thoracic surgeons—know much about empyema of the pleura; about its various causes, anatomical forms, clinical course, and its treatment by minor procedures or by major operations. To them empyema is nearly always regarded as a complication of some disease, either thoracic or remote. To them, also, it has always a serious aspect; one which is fraught with danger either remote or of startling and dramatic suddenness. But the great mass of our profession regards it as something that can be treated by standardized methods and the possibility of its dangerous complications is seldom considered or realized.

This is written for the information of those who do not confine their work to surgery of the chest. Practitioners of internal medicine may gain some new information and perhaps even a few of the general surgeons will get a new point of view.

Definition

According to Wilensky¹ we may regard all cases in which there is pus in any part of the pleural sac as empyema no matter what its direct or remote cause may be. Anatomically we speak of general, or of sacculated varieties, large or small, and these descriptive terms may also take in the sacculations according to their more exact location. For example, we have the mesial empyema which lies to the central

side of the lung, and the supraphrenic—which should be called hyperphrenic according to proper etymology. Sacculated empyema need not consist of a single collection of pus; there may be multiple empyemas and, indeed, I have found five distinct sacs during one operation with pure cultures of three different organisms.

Interlobar empyema is described by its title.

But if I am not to exceed the time allotted to me it is quite impossible to enter upon descriptive details. It is enough that I have called your attention to the various anatomical forms and I hope that I may have aroused interest enough to stimulate the investigational curiosity of some of my hearers.

Causes

The most direct cause of empyema is trauma from outside the body, such as a gunshot wound or a stab wound of the chest with or without injury to the lung but with implantation of pathogenic organisms. I shall not discuss this form of empyema.

The most frequent immediate cause of pleural suppurations is infection from the lung through a cortical abscess. This abscess is usually of inconsiderable size and often is unrecognized; or it may be metastatic from a distant focus. As an example I remember a case in which following a phlegmon of the arm there were blood-borne foci in the kidneys and

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 15, 1935

in both lungs. The focus in the right lung infected the pleura with a resulting large empyema. Within the other lung a closed abscess developed and was finally drained by operation without the production of pleural suppuration.

We may mention in passing another but less usual cause. I refer to the general infection of the serous membranes; e.g., in certain empyemas of influenza or of exanthematous diseases. I need not enumerate them.

Organisms

Infecting organisms are many. One of the commonest is the pneumococcus group of which there are numerous varieties. Empyema of this type is generally more easily treated than that produced by the streptococcus or the staphylococcus. Neuhof and Berck² have described most convincingly certain characteristics of staphylococcus empyema, with suggestions for its treatment. I have found that a streptococcus empyema must be regarded with profound surgical respect. The disease has a strong tendency to spread to other parts of the pleura either connected or not with the original focus and it also has a habit of recurring months or even years after the apparent healing of the operative wound. The streptococcus, too, has a way of invading neighboring structures and cavities such as the pericardium. There are cases in which an empyema, streptococcus or not, appears to invade the lung itself with resulting secondary abscess which may even enter a bronchus.

Bronchoscopy

This procedure is of great diagnostic and often of therapeutic value. It should be employed in every case of atypical disease of the pleura or of the respiratory tract. While it is seldom accompanied by actual pain the patient or, more often, the physician, is apprehensive and this attitude must be overcome by assurance that the knowledge gained through the endoscope may completely change the character of the contemplated operation or may even prove that no major surgical procedure is required. Unless the origin and distribution of the empyema are obvious, bronchoscopy should not be omitted.

Roentgenography

It is not fair to attempt to treat empyema, except in dire emergency, without having gained knowledge as exact as possible of the physical conditions with which we are dealing and we have nothing to aid us in this which compares in value with x-ray study. The usual x-ray picture (not fluoroscopy except in the hands of the elect) will give us information from which the proper surgical procedure may be selected.

There is no time here for a dissertation upon this subject but, speaking generally, we may determine the location of pockets or the presence or absence of gas.

Operative Treatment

If there is a history pointing to empyema and we are called to see a patient whose mediastinum is strongly deviated and who is cyanosed and gasping for breath it is obvious that some immediate action is necessary. This should be of the emergency type and should not be regarded as final even though it may occasionally result in complete cure. We have little or no time here for x-ray study, nor would it be of any particular value. The tension within the chest must be released and this, as is known, can be quickly accomplished by making a very minute intercostal incision through the skin and inserting a large needle into that intercostal space which seems farthest away from internal thoracic organs. A large tense empyema will usually push the lung and mediastinum so far away that danger to these regions need rarely be considered.* All the accidents from the mere insertion of a needle into an empyematous chest need not be enumerated but I will mention a few of the more obvious ones. The occurrence of mixed infection from the skin can be minimized by making a tiny incision as far as the subcutaneous tissues and inserting the needle through this opening. I prefer not to apply local anesthetics by injection but to benumb the skin either with one of the freezing vapors or even by applying a piece of ice through a covering of sterile rubber dam. The latter method is preferable in children.

* This refers only to acute cases.

because they are frightened by the sudden impact of the freezing spray. After the skin has been deadened and the tiny incision has been made it may be desirable to enlarge the opening. Efficient local anesthesia can then be secured by means of endermic injection, the needlepoint entering the skin by way of the minute incision without passing through the possibly contaminated cuticle. I usually select a rather large exploring needle for the thoracic puncture and in order that it may enter smoothly I lubricate it with a little 1 per cent or 2 per cent lysol.

Another danger to the chest wall is that of implantation of malignant anaerobes in the deep layers during the withdrawal of the needle. When this occurs it may be several days before the diagnosis of a phlegmon is made. Such infections put the patient in mortal danger and are far more frequent than is popularly supposed. A good way to prevent this accident is to inject a few drops of alcohol through the needle as it is withdrawn.

In these cases of acute tense pyothorax or pyopneumothorax the fluid should be permitted to escape without suction. There will be some entrance of air until normal pressure instead of positive or negative tension has been attained. While suction tends to correct mediastinal deviation it is always accompanied by the danger of too sudden correction of the displaced heart and great vessels, with the occasional dislodgement of a blood clot into the circulation with its consequent embolism. There is also a tendency to distend the lung so that it may be pricked by the needle point. Indeed, if strong suction is to be carried out one might better employ the tiny trocar and cannula which comes with the equipment of the Potam set. Then the lung will probably not be wounded even though it touches the cannula. An immediate examination for organisms by staining an ordinary smear will in the majority of instances furnish a provisional diagnosis. This may be of special importance if streptococcus or staphylococcus is found. Besides this if the pus is foul we may regard the case as anaerobic† and we should look for evidences of lung abscess. This means

not only physical examination but roentgenological observation as well. For the latter it is advisable to make x-ray exposures in at least two directions, first, anteroposterior or posteroanterior with the patient upright, and, second, the same direction of exposure with the patient lying on his well side. Fluid levels will nearly always demonstrate the size and form of the cavity and even the presence of more than a single chamber.

Fluid without visible levels, such as usually occurs before aspiration, is not always easy to recognize with the x-ray and may require the experienced eye of a professional roentgenologist.

When a fluid level is seen before any evacuation, either by aspiration or otherwise, one must conclude that there is either an opening into a lung abscess connected with a bronchus or that we are dealing with infection by gas-producing germs.

Certain cases of empyema not connected with a lung abscess by a large opening will occasionally recover following emptying with a needle. This is unusual but should be remembered so that in the least virulent forms operation may not be performed too soon after relief by the puncture method. Delay and even other punctures may at times be desirable. For example, in double empyema one would operate upon the side more seriously affected, and be content with a series of punctures of the other side until the patient's condition is good enough to permit bilateral drainage.

Open Operations

First we have intercostal drainage with a tube and valve. My preference after many years of experience is for an intercostal incision through the skin, then an opening with dissecting scissors into the pleural sac, taking care to keep as close as possible to the margin of the rib below. A soft gum tube just rigid enough to hold its lumen patent is the kind preferred. I do not countenance the use of the usual red rubber tube because it is nearly always hard in texture and its inner end may easily erode the lung or even the pericardium. This is particularly true in empyema accompanied by blood infection or resulting therefrom.

Drainage at the lowermost part of the

† There are also anaerobes which do not produce fetid gas.

chest, anatomically speaking, is neither necessary nor always advisable, because the diaphragm continues to rise with the formation of a long tract between the outside world and the collection of pus.

The suction which I employ is not the usual underwater type. Instead of this I use an extremely soft pliable finger cot, not a glove finger, which is fastened to the tube with a ligature. The end is slit so that with every cough abnormal pleural contents are forced out while with inspiration the finger cot blocks the tube. Should it be ascertained that we are dealing with an empyema secondary to lung abscess with bronchial connection this valve drainage will still function provided the caliber of the tube is larger than that of the opening in the bronchus. It is best to have the external part of the tube long enough to permit the finger cot to lie loosely in a bottle or other receptacle, and there must be a free space between the neck of the bottle and the tube. The finger cot should never be covered by a gauze dressing no matter how loosely because this impedes valve drainage. The lung expansion in these cases is amazing even though the valve does not work steadily or forcibly and when nothing is left but a narrow tract one may remove the tube and inject through a *much smaller tube* some antiseptic substance such as the irradiated petrolatum of Eising (Radolatum Squibb) or, especially in the tuberculous cases, 30 per cent iodoform in aquaphor (an animal substance and presumably absorbable). The Radolatum I have found of great value in producing closure of sinuses which have been discharging for many months. In inserting any substance, fluid or otherwise, through a sinus one must be absolutely certain that there is perfectly free egress of air alongside the tube otherwise the danger of air embolism is very great. As an added precaution these injections should be made with the patient's head distinctly lower than his chest.*

Drainage by a valve formed by a flap of skin with a short tube entering the chest beneath has been recommended and is worth considering in certain cases. An excellent paper on this subject by Dr. Alexander Nicoll³ of New York is well

illustrated and the physiological explanation is clear and accurate. It is applicable when the empyema occupies the greater part of the chest and there are no sacculations. I have never employed the method because the one just described by me seems simpler and more direct and if further procedures should be necessary they may be carried out by lengthening the original incision without the complication which the presence of a skin flap would entail.

Another word about drainage tubes. Deliberately repeating what I have many times emphasized let me insist that the intrathoracic part of a drainage tube must have numerous openings and that the most superficial of the openings should be close to the inner part of the chest wall. The frequency with which this simple rule is disregarded is almost inconceivable. Scarcely a month passes that I do not see a patient with a tube, the openings of which are far from the chest wall so that there is no actual drainage until the fluid has mounted almost or quite to the inner end of the tube. Merely replacing these tubes with multifenestrated ones has in a number of cases resulted in recovery without any secondary operation.

There is one other precaution; viz., be sure to use a tube of small enough caliber to prevent erosion of the edge of the next rib above. Serious or even fatal hemorrhages have occurred from an intercostal artery whose walls were eroded by a drainage tube.

If at the end of four or five days there are still signs of sepsis or if there is irritating cough another x-ray examination should be made immediately in search of secondary pockets. When these are found the case must be treated by wide intercostal incision or by resection of enough ribs to permit manual exploration of the chest with breaking down of adhesions, converting a loculated empyema into a single one. In considering the question of drainage in these cases I am convinced that a light packing of gauze into the entire sac even though this may be very capacious is of great value. The systematic application of this method was advocated by the late Dr. John F. Connors and Sauerbruch, in the 1925 edition of his book, describes a

* The valve drain permits ambulant treatment.

similar treatment* In from two to four days the gauze is removed and the amount of discharge will be found far less than one would have imagined. The lung can then be made to expand nicely by coughing which produces much more expansion than the usual blowing of bottles. In little children a pinch of snuff will cause sneezing when they cannot be made to understand the value of voluntary coughing.

Operative Therapy of Mesial and Supraphrenic Empyema

When a sacculation of pus is suspected just above the diaphragm it is essential to peel away the lower lobe from the dome of this muscle and even though pus is found here as a distinct sac it is best, so long as we are after all exploring, to break down mesial adhesions with the possibility of finding another sac or even an extension of the same one against the mediastinum, more often noted in chronic than in acute empyema. In any event one must be sure that the lung is free so that when the patient coughs or when the anesthetist creates hyperpressure, expansion may be unimpeded. In exploring the chest the possibility of interlobar effusions must be borne in mind and the lobes carefully separated.

Occasionally sacculations may require drainage through separate incisions. This is especially true in more malignant forms of infection such as those of hemolytic streptococcus for here the wide intercostal incision with consequent large denuded areas may invite fresh invasion, a small secondary incision is then best. In nearly all other infections this danger need hardly be considered.

Prognosis After Operation

The danger of a fatal termination in empyema is underestimated by the majority of physicians. Taken as a whole in adults and children anything better than 10 per cent may be considered statistically excellent. This includes those patients discharged from the hospital with a sinus who not infrequently require dangerous secondary surgical procedures for com-

plete restoration to health. Death after one of these operations must be ascribed essentially to empyema and not to the secondary operation because without this the patient would not be restored to health and the dangers of hemorrhage, cerebral complications, and amyloidosis would still be present—to mention only three of them.

No matter what the original cause of empyema may have been local recurrence may appear months or even years after operation, especially when the streptococcus was the invading organism. And here again, speaking of mortality, we must count in our list deaths following any operation for the cure of the empyema. This may be compared to the many "cured without surgery" cases of appendicitis with death following operation for a dangerous recurrence.

Let me give you an example. A man in his early forties had a left-sided empyema following pneumonia. He was operated upon in 1929 with apparent recovery. Three years later there was a recurrence from which he recovered in about five weeks after a second thoracotomy. He remained well for nearly three more years when the disease reappeared as a localized empyema. About five ounces of pus were removed now by incision and the left lung was freed from its tough and leather like pleural exudate so that its movements were unimpeded. The wound was to be treated open and a light packing was put in as a last step of the operation. The patient immediately expired. This case might have been twice counted among the so called cures.

How long we should wait before pronouncing one of these patients perfectly well it is impossible to say but one should be very cautious in assuming that any case of empyema is permanently cured. In the event of any subsequent inflammatory disease the chest should be examined by x-ray in order to exclude the presence of reactivated pleural infection.

Another complication of empyema which is very frequently found, especially in postponed operations, is the deformity of the ribs to which Bisgard⁴ has called special attention. He has found that in a comparatively short time, sometimes amounting only to days after the onset

*I have packed sacculated empyemas for many years, but have not recommended it as a standard procedure.

of empyema, the rib sections become distorted so that we have triangular instead of the usual flat costal sections. There is also a drawing-together of the intercostal spaces on the diseased side with corresponding spinal curvature to the opposite side or sometimes even to the same side.

The subsequent deformity or scoliosis may be very severe. Especially in children is this untoward effect to be guarded against even though they have made an apparently perfect recovery with a symmetrical figure. Later on in life the scoliosis may be responsible for a painful intercostal neuritis. The complication of this deformity should be kept in mind and the patient consistently observed and treated, if necessary, by orthopedic measures. One of the worst cases of this deformity which I have ever encountered appeared after a mere intercostal incision with rapid recovery in a baby less than a year old. I did not see the child again until she was eight and I was shocked to observe the ugly distortion, a direct result of negligence.

Pericarditis

Suppurative pericarditis is a complication of empyema, usually a fatal one, which is too infrequently diagnosed. We should have this disease in mind whenever the empyema itself does not account for the untoward symptoms. On March 10, 1935, at Mount Sinai Hospital at the Pathological Conference a case was reported in which postmortem examination had revealed the cause of death—suppurative pericarditis—when the x-ray pictures could not have been interpreted as

indicating the presence of pericardial effusion. The patient was a child and the empyema was a left-sided one.

In operating for suppurative pericarditis the great danger is wounding the pleura. When empyema is present the approach should be from the *empyematous side*, but extrapleurally, instead of from the opposite side regardless whether the right or left pleura was the seat of suppuration. I shall not discuss the technic of pericardiotomy here, though I wish to stress the fact that suppurative disease of the pericardium treated without operation is almost uniformly fatal.

Summary

(1) The object of this treatise is to stress the necessity for a working knowledge of acute empyema to both medical practitioner and general surgeon.

(2) A discussion of the causes of the disease and its gross anatomy.

(3) The importance of bronchoscopy.

(4) Roentgenography.

(5) Operative treatment according to cause and distribution.

(6) Discussion of drainage.

(7) Pericarditis as a complication.

(8) Prognosis.

NON-TUBERCULOUS PULMONARY SUPPURATION

CARL EGGERS, M.D., *New York City*

A study of non-tuberculous intrapulmonary suppuration shows that this condition is compatible with life, even for many years. How uncomfortable the patient will be or to what degree he will be disabled depends on his place of residence and mode of living, on the extent of involvement, the amount and odor of sputum, whether there is free communication with the bronchial tree or not, and on the condition of other organs. Patients who live an outdoor life are likely not to

feel the ill effects as much as those living in close quarters in the city, and they are not so likely to be obnoxious to their surroundings. They eventually succumb to their affliction, whether the immediate cause is directly traceable to the local lesion, such as hemorrhage, or extension of the process in the form of a bronchopneumonia or multiple abscesses, or to a pulmonary embolus; or to the degenerative effect of long-continued suppuration on other organs with general exhaustion,

or finally to distant complications such as brain abscess, meningitis, or liver abscess.

Every attempt should be made to cure patients in order to protect them against such a dreary outlook. It has been shown that unless conservative measures bring results in acute cases in a reasonable time, some more radical procedure or operative treatment is advisable. In chronic cases drainage is indicated in those patients in whom a cavity can be demonstrated, but in the other patients one is forced to the conclusion that operative intervention which aims at the actual destruction of the involved lung tissue, or removal of the lobe, is the only means to bring permanent cure.

For purposes of study and treatment it is practical to classify patients into groups, dividing them into acute and chronic cases, by bearing in mind that though they may differ as to etiology and early pathology, they may become more nearly alike as the process continues.

In addition to the consideration of the time element, however, it is believed that division into the following three main groups, is of value.

1 *Suppurations Limited to or Originating in the Bronchial Tree, Known as Bronchiectasis.* From the nature of the condition it is apparent that aspiration of foreign substances, infected or otherwise, is the probable etiological factor. The process may start insidiously or more acutely. At times the inflammation is confined to one lobe, or a portion of it, and remains there, at other times a gradual extension to other lobes can be made out until the process is bilateral in character. The lower lobes are affected more often than the upper. While in the beginning the inflammation is no doubt limited to the mucous membrane, leading to thickening and profuse exudation, it later spreads to the surrounding tissue and produces a pneumonitis and finally fibrosis. In those cases of aspiration in which putrefactive and pus producing organisms play a role, a destructive process may start early, leading to a rapidly spreading gangrenous abscess. In the less severe cases the walls of affected bronchi may become weakened, leading to a slow perforation with gradually developing secondary abscess, a so called bronchiectatic abscess.

2 *Suppurations of the Lung Parenchyma Outside the Bronchial Tree, Commonly Known as Lung Abscess.* They are less common than those of the first group. They may start in a pneumonic focus with breaking down of tissue and liquefaction. Much depends on the organisms involved. It is probable that pure pneumococcus infections infrequently lead to abscess formation. The latter is more common in broncho pneumonias of streptococcus or staphylococcus origin and where pus-producing organisms act as secondary invaders. Another common cause of these abscesses are septic emboli carried to the lungs through the pulmonary circulation. Another possible cause is an aseptic infarct which secondarily becomes infected. One also constantly has to bear in mind the possibility of a malignant tumor with breaking down and secondary infection, especially in older subjects. In case the infection is of low virulence, the abscess may become well encapsulated and pass into the chronic stage. Coincident with this development the walls become hard and sclerosed and eventually the entire process may resemble a bronchiectatic abscess. In the more virulent infections, on the other hand, the abscess steadily increases in size, there is destruction of tissue, possibly with gangrene. Eventually it may perforate into a large bronchus or the pleura.

3 *Massive Gangrene of the Lung.* This classification is reserved for those cases in which a portion of a lobe or an entire lobe becomes gangrenous and is extruded. It is due to blocking of a blood-vessel by a septic embolus or thrombus with massive destruction of the involved tissue. A secondary exudate will develop around this necrotic mass of lung and the clinical picture presented is that of an empyema, perhaps with signs and symptoms suggestive of an intrapulmonary lesion. The condition is not common, at any rate it is not often diagnosed.

What becomes of all these acute intrapulmonary suppurations if left untreated or if treated by medical, so called expectant treatment? One of several courses may be followed. (1) Some of the very septic cases, with high fever and prostration, run a rapid course and end fatally. They are nearly always associated with

spreading gangrenous inflammation, (2) A certain number of the milder forms heal spontaneously. In some of these the true pathology may not have been recognized. They may have been diagnosed as pneumonia with delayed resolution, chronic pneumonia, or putrid bronchitis. However, there are also real lung abscesses or early bronchiectasis cases, recognized as such, which go on to complete cure. (3) Some abscesses perforate into the pleura. This is not an infrequent occurrence with those situated near the periphery. If the perforation is small, a slow leak results with a well encapsulated pocket of pus. In case it is larger, a regular empyema forms, which sinks to the lower part of the pleural cavity. Sometimes a sudden perforation takes place, especially during a coughing effort, resulting in an acute pyopneumothorax, or a perforation into the pleura and bronchus may take place at the same time. (4) The suppurative process may gradually pass over into the chronic stage. In case it is limited to the bronchi, bronchiectasis results. If on the other hand, the inflammation is situated in the parenchyma, it may spread and gradually involve more and more tissue, or it may encapsulate and become quiescent with occasional flareup.

At any time during this acute period, danger threatens the patient. How great the danger is depends on various factors, whether the infection is limited to the bronchial tree, or whether it is spreading in the lung parenchyma, also on the virulence of the organism and the resistance of the patient, whether the supuration is near the hilus or near the surface of the lung, and whether blood-vessels are involved in the process. A complication may develop unexpectedly and interrupt what seemed to be a satisfactory convalescence. A sudden pyopneumothorax may terminate fatally, there may be a severe hemorrhage, a focus of secondary pneumonia may develop, pulmonary embolism may result, or infection may be carried by a pulmonary vein to the heart and through it into the systemic circulation to form a brain abscess or other secondary focus.

It is apparent therefore that alert watchfulness is in order, and that intervention may become necessary at any time. As long as convalescence is satisfactory, and

there is slight steady improvement, one should carry a patient along until cure results or to a stage when the acute symptoms have been overcome and the danger of spreading sepsis reduced. Such conservative treatment may be materially enhanced by postural drainage, perhaps a transfusion and at times a salvarsan injection.

If in spite of these measures no improvement takes place, or the condition tends to gradually get worse, some form of more active interference has to be considered. This applies alike to the rather acute cases which remain stationary, and to those patients who come under observation after they have reached the chronic stage.

As there is considerable difference in cases with lung suppuration, it is well to consider the more active treatment under the headings of three large groups mentioned above.

Treatment of Bronchiectasis. Much depends on whether the case is seen early or late, whether it is limited to one lobe or bilateral in extent, and whether it is still confined to the bronchi. In those cases in which the infection is limited to the bronchial tree, with small cavities due to dilatation of some of the bronchi, and regardless of whether the surrounding lung parenchyma is infiltrated and fibrosed or not, the object to be achieved naturally is to try and favor drainage by way of the bronchi. Postural treatment is of great help, as all the infected bronchi communicate with the larger trunks. Inhalations to help fluidify the secretion and make it less odorous are of value. This treatment may be supplemented by bronchoscopic therapy. By dilating strictures, cauterizing granulations, and sucking out tenacious secretion one may open up paths for better drainage. It is also possible to inject antiseptic or astringent solutions to favor healing. In the very early cases one may even remove the offending infectious agent which has gained entrance by aspiration, and thus abort the process. Bronchoscopic studies after mouth operations have shown that in many cases blood and secretion is found in the tracheobronchial tree and that apparently it is not the aspiration as such which does harm, but the fact that it cannot be expelled in certain patients, owing to some impair-

ment of the expulsive mechanism. If this is conceded to be true, it is evident that early bronchoscopy aimed at the removal of such aspirated potentially infective material, should cure these cases.

It is known that bronchiectasis is at first often a localized lesion, and that later one bronchus after another becomes infected, until an entire lung or both sides are involved. It is very desirable therefore to utilize all means to combat the disease in this early stage, and there is at present no method equal to or superior to bronchoscopy.

If these measures fail, artificial pneumothorax may be tried alone, or in conjunction with bronchoscopy. If we consider that one of the reasons for failure is the inability of the lung to collapse and empty itself owing to the negative pressure in the pleural cavity, it is conceivable that compression or collapse will favor drainage via the bronchial tree. This method has been tried by a number of authors, and it is felt that at times it may be of help. Like every other method of treatment, it is probably of real value only in the suitable case. It should be used especially in early cases in whom no serious structural changes have taken place in the bronchi. It seems logical that the requirements for success would have to be a free communication with the bronchial tree, that there should be no pleural adhesions, and that the lung tissue surrounding the infected bronchi must be resilient, soft and collapsible. In cases with marked infiltration of the lung parenchyma, sometimes called suppurative pneumonitis, which is incapable of compression or collapse, the treatment will naturally be of little value. The same applies to old chronic cases with fibrosis.

If no result is obtained, other means to bring about compression of the lung may be resorted to. Crushing of a phrenic nerve may be performed, or finally some form of surgical collapse, so called extrapleural thoracoplasty. The extent of this would have to depend on the extent of the intrapulmonary lesion. This operation is usually applied in the more chronic cases with extensive unilateral involvement. It does not cure, and some authors have little faith in it, but it sometimes brings about amelioration of symptoms. In patients with profuse foul smelling

sputum relief is sometimes obtained by the use of x-ray treatments.

If all these measures fail, is there anything left to do, or should anything else be done? Much depends on the condition of the patient. If he has been improved considerably by bronchoscopic treatment or a collapse operation, if the amount of sputum has been diminished and is non-odorous, the best advice is to be satisfied. If on the other hand there has been no improvement, if the sputum is copious and of a disagreeable odor, making the patient's life miserable and him practically an outcast, some more radical step may be proposed, either a direct approach to the suppurative focus or a lobectomy. The cases in which these operations are indicated are naturally those with a unilateral lesion and preferably those with involvement of only one lobe.

By direct approach is meant an operation via the thoracic parietes directly into the suppurating lobe. In true bronchiectasis, as we consider it today, a drainage operation would seem to be of little value, because not all infected bronchi can be reached. In actual practice, however, it has been found that a bronchial or pulmonary fistula established in the center of the lesion may by external drainage and aeration do away with the odor and improve the general well-being to such a degree as to almost amount to a cure.

If more radical treatment is indicated one may use the so-called "Cautery Pneumectomy," which consists of the gradual destruction of the affected lung tissue with the cautery. The method has not become popular because the extent of destruction is not definitely under control and because of the frequency of secondary hemorrhages. In some cases, striking results are obtained.

The actual removal of the affected lobe or the entire lung by means of surgical excision is becoming more popular. For years this has been recognized as the ideal procedure in rebellious cases, but its application was retarded by the high mortality. Several methods have now been developed to insure greater safety, either by the one or multiple stage procedure, and it seems that this will become the method of choice.

Treatment of Lung Abscess. In cases of bronchiectasis in which the infection has not remained confined within the dilated and sacculated bronchi, but has broken through and invaded the surrounding lung parenchyma in one or more places, bronchiectatic abscesses result. Such perforations may result early and lead to rapidly spreading gangrenous abscesses, especially in those aspiration cases in which putrefactive and pus-producing organisms have entered. As a matter of fact, the bronchiectasis has hardly time to develop before perforation takes place. In other cases the infection remains confined within the bronchi for some time, and then a slow perforation takes place and gives rise to a gradually developing abscess. Both these types should then no longer be classed with bronchiectasis, but with the lung abscesses produced in other ways. They should, however, be given the benefit of conservative treatment and bronchoscopic therapy, for it is particularly in this group of acute postoperative abscesses that spontaneous cures are reported.

In a general way it may be said that the acute type of these abscesses with rapidly progressing destruction of lung parenchyma and liquefaction belong in the same class as acute lung abscesses following pneumonia or embolism, and require the same treatment. Lung abscess proper, meaning by that a collection of pus in the lung parenchyma, originating in either of the ways mentioned above, is a truly surgical condition, and drainage alone will bring about a cure, either by way of the bronchial tree or through the chest wall. Nature may bring about such drainage by perforation into a bronchus or into the pleura, and thus lead to a cure. If it does not, it is up to the surgeon to establish drainage.

At what time in the course of the disease should he intervene? That is a question not easy to answer. I think all thoracic surgeons are agreed that the earliest time consistent with safety is the best time, as it is most likely to lead to complete restitution to normal. Operations done very early during the acutely septic stage of the disease have a very high mortality and should be avoided. Then also one should give nature a chance. If we consider the pathological

process within the lung to be a gradually progressing destructive one, it is possible to conceive of the process reaching either a large bronchus or the pleura and producing there adhesions to the parietal pleura which makes operations much safer, or an empyema, which, according to reported statistics, leads to a high percentage of cures. Just how long one should wait has to be judged in the individual case. The majority of authors seem to feel that if no improvement or cure has resulted in two or three months, operation should be considered. If at any time during this period the condition gets worse, or the indications are clear-cut, operation should be done earlier. No definite rules can be laid down, but it may be said that it is wise not to let a patient get into the chronic stage, because in this period many more complications threaten and a restitution to normal, even after operation, is longer drawn out and often impossible.

In those patients in whom the lung has become adherent, and in whom local signs can be elicited on physical examination the entire operative procedure may be carried out in one stage. It is best to resect a piece of one or two ribs, and after making sure of the location by an exploratory puncture, go right in alongside the needle. By means of a finger, the opening may be enlarged and all the necrotic material and pus evacuated. If there is much bleeding a tampon should be packed into the cavity, otherwise a soft rubber tube or rubber dam should be inserted. In the more acute cases, those operated on within a few months after onset, one finds an irregular ill-defined cavity, with strands or septa running through it. The amount of pus and necrotic material found in these cases indicates that no free bronchial communication ever existed, at least not of a size sufficient to carry out this material and shows the futility of conservative treatment in such cases. In case the lung has not become adherent, but the location of the abscess is superficial and has been definitely localized, a circular suture approximating the two pleural layers may be done, and a tampon then lightly packed into the wound for several days, when an opening is made into the abscess within the limits of the circular suture. Instead

of a suture, one may simply pack gauze against the pleura, which will favor formation of adhesions. More difficulty is experienced in those patients in whom no adhesions have formed. The abscess is usually situated deeply, and not easy to localize. It is necessary to open the thorax, palpate the lung, and after finding the infiltrated area, suture the overlying visceral pleura to the parietal one. It is important to choose the proper place for the incision, so that the abscess comes to lie directly underneath. The procedure carries with it more danger than in the other cases and usually has to be performed under general anaesthesia.

In the chronic lung abscesses the danger of sepsis is usually less, while hemorrhage assumes a more important role. The surrounding lung tissue is firm and sclerosed, and has lost its elasticity, the bronchi are dilated, rigid and infected, and the blood vessels friable. There is usually a well-defined fluid level. The lung may be adherent or not. On this largely depends whether the operation should be done in one or two stages. The condition of the patients also has to be considered in deciding the question, for they usually cannot stand very much and care must be taken not to overtax their strength. For this reason alone a two stage operation offers advantages.

While in the more acute cases healing usually takes place fairly early after operation, it is often long drawn out in the chronic cases, and a bronchial or pulmonary fistula has to be maintained for a long time, or even permanently. One reason for this is that old cavities become lined with epithelium which is continuous

with that of the bronchi and prevents obliteration. Another reason for delayed healing is found in the lung tissue surrounding the old abscess cavity, which is infected and contains numerous little recesses filled with material which keeps up a mild suppurative process. The fistula thus acts as a permanent safety valve. Although not ideal, the results of drainage in these old cases are nevertheless so gratifying that the little discomfort is fully compensated for. Lobectomy would be the operation of choice were it not for the high mortality.

After the fistula has existed for months or years, and no longer discharges pus, but simply a little mucus, and the x-ray shows a clear field, one may consider that it has fulfilled its purpose and allow it to close spontaneously, which in many instances it will do as soon as the tube is removed. In some cases, however, there are definite obstacles to closure and one has to operate.

Treatment of Massive Gangrene of the Lung. Knowledge of the pathology, suggests the treatment of this condition, which is thoracotomy with removal of the necrotic mass. Unfortunately the diagnosis cannot be made unless one operates. The clinical picture is that of an empyema, and at operation for this condition the demarcated lobe, or portion of lobe, is accidentally discovered. This is perhaps an argument in favor of making empyema incisions sufficiently large to be able to look in. The prognosis is not necessarily bad, especially if operation is done fairly early and if the amount of lung tissue involved is not large.

850 PARK AVENUE

THE DIAGNOSIS AND SURGICAL TREATMENT OF ANTERIOR AND POSTERIOR MEDIASTINAL TUMORS

Report of a Case of Posterior Mediastinal Tumor

STUART W. HARRINGTON, M.D., Rochester, Minn.

Division of Surgery The Mayo Clinic

Increased interest in the surgical treatment of mediastinal growths has been shown in recent years because marked advancement in methods of diagnosis of thoracic diseases has made possible their early recognition. Often many difficult problems are associated with establish-

ment of a definite diagnosis of mediastinal tumor and with selection of the type of treatment to be instituted for them. These problems are best solved by close co-operation of the clinician, the roentgenologist, and the surgeon.

The occurrence of mediastinal tumors

has been known for many years but until recently their clinical recognition as a rule was attained so late in the course of the disease that surgical treatment was seldom possible and rarely successful. The advent of roentgen rays made possible the early recognition of these tumors before they have made serious inroads on the patient's general health. This has been an important factor in the successful results obtained from complete surgical removal of these growths. The older view was that most of these tumors were malignant. Such studies were based on cases of long standing. Early surgical removal of these growths has proved that a relatively high percentage of the lesions are benign. Nevertheless, I believe that all of these growths can become malignant and that the reason a high percentage of benign tumors has been seen in recent years is that they have been removed early, before they had undergone malignant change.

Differential diagnosis of these growths requires correlation of all of the available methods of diagnosis of thoracic disease. The clinical manifestations of these tumors are often meager and rarely pathognomonic, although they are always of value, when correlated with the laboratory findings, in establishing a final diagnosis and in determining the type of treatment to be instituted. The subjective symptoms and physical findings are rarely diagnostic but are often of value in determining the presence, situation, and probable type of lesion.

Tumors situated in the anterior mediastinum as a rule cause more subjective symptoms than those situated in the posterior mediastinum, because of the smaller space in which they are confined. This is true whether the lesion is benign or malignant. Pain is one of the most important subjective symptoms of these growths. Anterior mediastinal tumors usually are accompanied by pain, whether they are benign or malignant, but the pain of benign tumors is never as severe as that associated with malignant lesions. When lesions are benign there is a sense of pressure beneath the sternum, usually associated with dyspnea on physical effort. These symptoms are progressive in character, and are associated with, and augmented by, inflammatory lesions of

the respiratory tract. The tumors are commonly diagnosed as pulmonary or pleural lesions, such as pleurisy, pneumonia, or influenza. When anterior mediastinal tumors become malignant, the pain is usually more severe, at first occurs periodically, and is noted mostly at night. It gradually becomes more or less constant, until sedatives are required for relief.

Posterior mediastinal tumors may be benign or malignant. When benign, they are the most silent tumors that occur within the thorax. The outstanding clinical features are relatively few and mild symptoms, associated with large growths, for these tumors may fill practically the entire hemithorax without producing any marked symptoms other than dyspnea on exertion. When tumors situated in this region are malignant, or have undergone malignant change, relatively small growths are associated with severe pain; the patient's chief complaint is of the pain. Dyspnea and other clinical manifestations are usually more marked when the tumor is situated in the upper part of the posterior mediastinum, because in this region the growth not only produces pressure on the lung itself, but in many instances it causes direct pressure on the large bronchi and on the hilus of the lung; at times, also, it exerts pressure on the trachea, causing marked interference with respiration, particularly on exertion. With this latter condition there is often associated compression of the esophagus that causes some difficulty in swallowing.

Bronchoscopic and esophagoscopy examinations often are aids in establishment of the diagnosis by disclosing the presence of an intrinsic tumor which causes pressure on the bronchus or esophagus. These examinations are rarely conclusive. Thoracoscopic examination, after induction of artificial pneumothorax, may be of value, and a definite diagnosis often can be made by removal of a portion of the tumor through the thoracoscope. In most instances, however, sufficient information can be obtained from the more conservative methods of diagnosis to determine the advisability of surgical intervention; in such cases I prefer to perform exploratory thoracotomy.

The most important of the clinical

methods of diagnosis is roentgenologic studies, which require roentgenograms taken in different positions as well as roentgenoscopic examination of the thorax. The single roentgenogram is of little value in the surgical consideration of these tumors, for it determines only the presence of the tumor and its position in one plane of the thorax. Anteroposterior and lateral stereoroentgenograms are of great aid in determining not only the situation of the tumor in the thorax, but also the relation of surrounding normal structures to the tumor and any encroachment that the tumor has made on these structures. Anteroposterior stereoroentgenograms are especially accurate in determining the situation of the tumor in the vertical plane of the thorax, and the lateral films are particularly accurate in determining the relation of the tumor to the anterior and posterior thoracic walls. Roentgenoscopic examination does not furnish as much detail as do stereoroentgenograms, but it is of great value in determining the normal functional activity of intrathoracic structures, and any impairment of these structures which may have been caused by the tumor. It is especially important in differential diagnosis of aneurysm from anterior mediastinal tumors. Here the differential diagnosis is often made difficult by the adherence of dermoid cysts and teratoid tumors to the pericardium and great vessels, which causes transmitted pulsation. Horizontal roentgenograms are of value in selected cases; they are taken in different positions to determine fluid level within the pleural cavity or within the walls of a cystic tumor.

In many cases the diagnosis is still obscure even after roentgenoscopic examination and the taking of an entire series of roentgenograms in different positions. In some of these cases, additional information can be obtained by taking another series of roentgenograms after production of artificial pneumothorax, or after introduction of barium into the esophagus, and, in some instances, of iodized oil into the bronchial tree. It is important that the same technical methods, particularly as to the distance of the patient from the film, be used in cases in which patients are being kept under observation or treatment, so that any change

in the size of the roentgenologic shadows will be caused by variation in the size of the lesion and not by variation in technic.

Radiation therapy is often of great aid in the differential diagnosis of radiosensitive tumors. This is of particular importance in the selection of cases for surgical intervention, for one of the most important lesions to rule out is mediastinal lymphoblastoma. These growths are not amenable to surgical treatment, and in the roentgenograms they can simulate the appearance of practically any other primary intrathoracic growth. A definite diagnosis of lymphoblastoma often can be made by complete roentgenologic study. In cases in which there is any doubt, roentgen therapy should be utilized, for these tumors are radiosensitive and will rapidly diminish in size, and practically disappear, in a relatively short time. Some diminution in the size of the roentgenologic shadow of the growth can be noted as early as three to five days after the initial treatment.

Although roentgenologic studies of the thorax may be said to give the most important evidence in the clinical diagnosis of mediastinal tumors, they are of even greater importance in those cases in which surgical treatment is considered. Not only do they assist in selection of operable growths, but also they aid in determining the most accessible type of approach to the tumor and in determining the presence of conditions that might, after operation, become complications.

The most important considerations in the surgical treatment of mediastinal growths are early diagnosis, preoperative preparation of the patient, selection of the most accessible method of approach, application of adequate mechanical means for maintaining intrapulmonary pressure, complete removal, and postoperative care of the patient. The significance of early diagnosis of malignant growths is obvious. With benign growths it is important to institute surgical treatment before the tumor has encroached on important structures within the thorax, or before it has attained such great size that the operative risk is greatly increased. The immediate operative risk is often decreased by inducing preliminary artificial pneumothorax, which permits the patient to

become accustomed to the unilateral alteration of pulmonary pressure. This procedure cannot be carried out in those cases in which the lung is adherent to the tumor or thoracic wall, for the adhesions prevent collapse of the lung by air pressure. In cases of anterior mediastinal tumor it is rarely advisable to attempt artificial pneumothorax because all of the growths are firmly adherent to the thoracic wall, lung, and mediastinal structures, and there is danger of injury to the underlying structures when the needle is introduced into the thoracic cavity. In cases of posterior mediastinal tumor the growth is rarely adherent to the lung until it attains considerable size, unless it is malignant. The lung is adherent to malignant growths even when they are small. However, when artificial pneumothorax can be induced, this should be done three to five days before operation.

Much of the advancement that has been made in surgical removal of intrathoracic growths has been accomplished because of marked improvement in the administration of anesthetic agents. The greatest immediate danger in intrapleural operation is open pneumothorax, with collapse of the lung. This may produce severe respiratory and circulatory disturbances which may result in sudden death. These dangers have been practically eliminated by the use of intratracheal anesthesia, induced by means of an apparatus by which gas and oxygen are administered under positive pressure. I prefer cyclopropane or ethylene gas as the anesthetic agent. Administration of the anesthetic should be in the hands of a skilled anesthetist. In cases in which partial collapse of the lung is required, the lung should be permitted to expand fully every five to ten minutes during the course of the operation. A suction pump should be applied to the intratracheal catheter before it is withdrawn, to remove any mucus that may have accumulated in the trachea. It may be stated that use of intratracheal positive pressure anesthesia has been of the same relative importance to the technical problems associated with surgical removal of these growths as roentgen rays have been to the clinical diagnosis of the lesions.

The chief technical difficulties associated with surgical removal of these

growths are as follows: (1) Access is through the bony encasement of the thorax, and a method of approach must be selected that will give the greatest exposure of the tumor with the minimal amount of trauma to the thoracic viscera and thoracic wall; (2) traction on the important structures in the mediastinum, to which the tumor might be adherent, is an element of danger, and (3) complete reconstruction of the thoracic cage, so as to restore the normal relations of the thoracic viscera and to give the minimal amount of deformity, is advisable.

The methods of approach to and the types of operative procedures for mediastinal growths depend on the site of the tumor, its extension within the thoracic cage, and the presence of complications which may have been produced by the growth. Each case must be considered individually, depending on the indications presented. A few general principles apply to all cases. The most important is early operation and complete removal of the tumor; this may be performed in multiple stages but I prefer to remove the growth in one stage if possible, for the second operation may be more hazardous and difficult than the first. Incomplete removal of the growth may be followed by more serious trouble and usually subsequent operative procedures will be required.

The approach to anterior mediastinal tumors may be through the anterior or posterior wall of the thorax, but I prefer the posterior approach, particularly when the tumor projects into either pleural cavity, because much greater exposure can be obtained than by the anterior approach and the important structures to which the tumor is adherent, usually the heart, the great vessels and the lung, can be carefully dissected from the growth under direct vision. Any injury to these structures caused by the tumor or operative procedure can be detected and repaired immediately, and if infection is encountered drainage can be instituted readily. If the tumor is small and is confined within the anterior or superior mediastinum, or has ruptured into the lung anteriorly, the growth may be more accessible through an anterior approach, either by splitting the sternum or by resecting the cartilage and turning back the wall of the thorax. In some instances

the tumor can be removed extrapleurally through this anterior type of incision, while in all cases in which the posterior approach is used, the operation is transpleural. In this series of cases of anterior mediastinal tumor, twelve of the growths were teratoid, of which five were of the dermoid type, one was classified as a parasitic fetus because of its highly organoid structures, and two were squamous cell epitheliomas, malignant change having taken place in original teratoid growths. The anterior approach was utilized in three cases and the posterior approach in nine. The tumor was removed transpleurally in eleven cases and extrapleurally in one. There was one operative death in a case in which the growth was malignant. Eleven patients recovered from operation and were completely relieved of symptoms.

The approach to posterior mediastinal tumors is practically always through the posterior thoracic wall, and an attempt always should be made to remove the tumor extrapleurally. This, however, rarely can be accomplished and only in cases in which growths are small, for the tumor usually is adherent to the parietal pleura, which is ultimately opened, in some instances the tumor is placed so far back in the mediastinum that it is impossible to dissect the pleura away from the thoracic wall sufficiently to permit removal of the tumor.

The situation of the incision in the thoracic cavity depends on the site of the tumor. In all cases in which the tumor is situated in the posterior mediastinum, a posterolateral incision is made around the vertebral border of the scapula. The entrance into the thoracic cavity is made by partial resection of one rib, over the most central portion of the tumor. The thoracic cavity is then opened by incising through the periosteum and pleura in the bed of the rib. The tumor and its attachments in the pleural cavity are then explored, and if further exposure is desired, it can be accomplished by partial resection of an adjacent rib. In some cases in which there is a small tumor, or a collapsible cystic tumor, the growth may be removed through this small opening. If a larger opening is required, for a large solid tumor, the bordering ribs, both above and below the resected rib, are cut

and drilled, and at completion of the operation the cut ends are sutured together to reestablish the contour of the thoracic wall. Extreme care should be taken not to injure the structures to which the tumor is adherent within the thorax. There is always a fairly definite capsule over the tumor, which consists of pleura and a thin capsule of the nerve sheath.

This capsule contains many large vessels if the tumor is large. By careful dissection, this capsule usually can be separated from the adherent lung without producing any great injury to the lung. In some of the cases in which large tumors are very adherent to the lung, it is necessary to dissect the lung away from the tumor, and careful hemostasis, involving attention to the vessels on the surface of the lung, is required. Posteriorly these tumors are often very adherent around the aorta, particularly on the left side, and great care should be exercised not to injure the wall of the aorta. Also, care must be exercised to ligate the intercostal vessels that may be severed in the course of removal of the tumor. It is important to leave in place the posterior portion of the capsule of the tumor, to cover over the raw surface which is left in the parietal pleura after the tumor has been removed. The greatest difficulty in hemostasis is often encountered posteriorly, in dealing with intercostal vessels. In some cases, in which some erosion of an intervertebral foramen has taken place, hemorrhage may occur from dilated vessels in the spinal cord.

Tumors situated in the posterior mediastinum and spinal cord, so called dumb bell tumors, are removed by posterior mediastinotomy and laminectomy, which are performed at the same operation. This procedure, although carrying greater immediate operative risk because of the two operative procedures, is a more advisable procedure than the two stage operation because it avoids the possible complication arising in leaving a portion of the tumor, this may be very hazardous. Dr. Craig and I recently removed a tumor of this type with excellent result. This case has been reported elsewhere.¹

In this series of 35 posterior mediastinal tumors, there were 19 fibroblastomas, 4 of which had undergone malignant

change to sarcoma, 4 endotheliomas, and 12 chondro-osteosarcomas. The anterior approach was utilized in 4 instances and the posterior approach in 31 instances. All tumors were removed transpleurally. There were 4 operative deaths. Thirty-one patients recovered from operation. All of the patients whose lesions were benign have been completely relieved of symptoms. There have been 9 subsequent deaths from recurring malignancy, and the average postoperative duration of life in these cases has been 3 years and 7 months. Seven patients who had malignant growths are still living, one of whom has lived more than 10 years without evidence of recurrence.

Postoperative care is of the utmost importance. Particular care should be taken to maintain the blood pressure and to relieve any respiratory difficulty. It is usually advisable to give some form of medication intravenously, either during the operation or immediately afterward. If much blood has been lost, a transfusion of blood should be given; if this is not practicable, infusion of solution of acacia is satisfactory. Respiratory difficulty is the most serious immediate complication, and is best relieved by placing the patient in an oxygen cabinet. This is often a life-saving procedure, for sufficient oxygen can be obtained to tide the patient over the most critical postoperative period of respiratory embarrassment.

Report of a Case

A man, aged 45, came to the clinic March 8, 1934, chiefly because of arthritis of one year's duration, and to obtain advice as to the thoracic condition which had been discovered in the course of a routine examination made prior to his arrival. A roentgenogram of the thorax at that time had revealed a large shadow in the lower left portion of the thorax. He had had no pulmonary signs except a moderate morning cough which he thought was attributable to excessive smoking.

Physical examination revealed that the man was well developed and well nourished. He weighed 165 pounds (75 kg.). Examination of the thorax revealed slight dullness and diminished breath sounds at the left base and many whistling râles at both apices, especially on inspiration. Both ankles were swollen and stiff and both knees were swollen. Clubbing of the fingers and toes was present. The systolic blood

pressure was 128 mm. of mercury and the diastolic, 88. Urinalysis disclosed a specific gravity of 1.034, an acid reaction, absence of sugar and albumin, and an occasional leukocyte. The concentration of hemoglobin was 88 per cent. The flocculation test for syphilis was negative.

In a roentgenogram, a large, circumscribed shadow was seen in the left lower part of the thorax. The lateral view revealed the large tumor to be posterior, and that bone was not involved (see Fig. 1).

The man returned home to undergo physiotherapy because of the arthritis, but he returned to the clinic April 11, 1934, to submit to surgical intervention for the mediastinal tumor.

April 14, 1934, under intratracheal ethylene and ether anesthesia, left mediastinotomy was performed. A posterolateral incision was made between the seventh and eighth ribs. The posterior half of the eighth rib was resected first, and the tumor was exposed immediately. The posterior half of the seventh rib was then removed and the tumor was completely removed extrapleurally. The tumor seemed to originate between the seventh and eighth ribs, in the posterior mediastinum, and filled the entire lower left thoracic cavity, causing complete collapse of the lower lobe of the lung and partial collapse of the upper lobe. It extended across the entire thoracic cavity and caused considerable pressure on the heart and pericardium to which it also was attached. There were multiple bleeding points throughout the posterior mediastinum, from the visceral and parietal pleura, to which the tumor was firmly attached. These bleeding points were all ligated with catgut. This was done without opening into the pleura at any point. The lung was inflated as much as possible and the air was aspirated from the posterior mediastinal pocket, by suction, while the wound was being closed. The inner layer of the periosteum of the eighth rib was sutured, obliterating the posterior pocket as much as possible. The thoracic wall was completely closed without drainage.

The tissue removed was a neurofibroma, measuring 14 by 13 by 8 cm., and weighing 825 gm. (see Fig. 2).

Convalescence was entirely uneventful. The man was dismissed from our care on the eighteenth postoperative day, at which time his wound was entirely healed (see Fig. 3). He returned for observation five months following his operation, at which time he was enjoying excellent health. He had gained 21 pounds (9 kg.). The roentgenogram of his chest at this time revealed evidence of the preceding resection of the seventh and eighth ribs, a thickened pleura

at the left base, and negative pulmonary fields (see Fig. 4).

Summary and Conclusions

The clinical symptoms, surgical treatment, and operative results in 47 cases of anterior and posterior mediastinal tumors are summarized. One case is reported in detail.

Recognition of these growths by roentgenologic studies has made possible their early surgical removal, and microscopic study of them has shown that a relatively high percentage are benign, although they all may undergo malignant change.

Roentgenologic studies are of great value in selection of patients for surgical treatment, and in cases in which operation is found advisable such studies are of great aid in determining the situation of the growth and the type of operative approach to be used.

Surgical removal offers the only hope

for eradication of the disease, and it should be instituted early, before complications have occurred, for these increase the hazards or influence the results of the operative procedure.

The operative risk is not great, considering the magnitude of the operation, for in the 47 cases, in many of which the tumors were huge, there were only 5 deaths. In these 5 cases in which the patients did not survive operation, complications had occurred before the patients came to operation, and these complications played an important part in the inability of the patients to survive the operative procedures.

SURGERY IN PULMONARY TUBERCULOSIS

The Present Status

FRANK BERRY, M.D., *New York*

Associate Surgeon, Bellevue Hospital and Fifth Avenue Hospital

Notwithstanding the rapid increase and spread in the application of surgery to pulmonary tuberculosis during the past quarter century, there is still much unacquaintance and confusion among the profession as a whole as to the position of surgery in this form of tuberculosis. Among the specialists even there is still a small group who see through the glass darkly as well as those at the other extreme of too great optimism and facile confidence. The present discussion will offer nothing new nor will it have to do with statistics; rather it will attempt to describe the several accepted surgical procedures, together with their indications and chances of success, that are employed in the present-day treatment of phthisis.

But first I would emphasize, as my major premise, that tuberculosis is a general systemic disease. It may attack several parts of the body simultaneously even though the recognized manifestations appear quite local. The organism

always responds as a whole, however, and it is this response that must be considered first and foremost in evaluating the selection and prognosis of surgical therapy. The chance of a favorable outcome by surgery varies directly with the propensity for repair and stabilization in any given case. This is shown by a temperature below 100° F., a steady pulse below 100, lack of anemia or dyspnea, and a gain in or maintenance of weight—absence of toxemia. In the presence of progressive activity and toxemia the risk of any surgery increases and the outlook becomes correspondingly poor. Surgery, therefore, offers most in the stabilized case with fibrosis, either with open cavity and positive sputum, or with repeated hemoptyses without other untoward signs of activity—in other words the good chronic.

All of the surgical procedures are based upon the principle of collapse therapy. This is best exemplified by pneumothorax, proposed in 1820 by James Car-

son, and first practiced in 1882 by Forlanini. The idea of artificial pneumothorax was originally conceived from the observation that certain cases of pulmonary tuberculosis did well following the establishment of a spontaneous pneumothorax. The procedure was slow in gaining popularity, but it has now been so widely adopted that only passing mention need be made. Due to the establishment and maintenance of artificial pneumothorax many people with tuberculosis, who would otherwise be confined to bed or sanatoria, have been enabled to live normal and gainful lives while their cure was in process. Again some of the most brilliant results of pneumothorax have been attained in the acute florid pneumonic form of the disease, for without the benefit of pneumothorax most of these patients would have succumbed.

The lung contains abundant smooth muscle and elastic tissue, which tend to contract concentrically about its center of gravity, a point lateral to and somewhat below the hilus. A properly established pneumothorax in a pleural cavity free from adhesions abolishes the opposing pulls of the chest wall and diaphragm in respiration and permits the lung to contract. With the destruction of the normal lung tissue by disease and owing to the normal retractility of scar tissue when present (provided this is not too dense) still further collapse is obtained of the affected portion of the lung and the walls of cavities approximated. Not only is added rest afforded with the closure of cavities, but also the lymphatic circulation is slowed, the tendency to spread is checked, toxemia diminished, and healing and fibrosis are promoted.

Internal Pneumolysis

The chief difficulty encountered in pneumothorax therapy is the presence of adhesions, which perforce render the establishment of the pneumothorax more or less incomplete and ineffective depending on their location, character, and extent. It is because of these adhesions that most of our present day surgical procedures have been developed. Collapse of the affected portion of the lung may be interfered with on account of a firm and widespread synechium between that portion, or the entire lung, and the chest

wall, or the adhesions may be localized as cords, bands, strings, and folds of pleura. If these can be removed, the pneumothorax may be rendered effectual and as complete as desired. Attack may be made upon them by stretching and the use of a tension or pressure pneumothorax, or attempts may be made to divide them surgically—the Jacobaeus operation of internal pneumolysis first described in 1916.

To quote from Matson:

The first requisite is that the case be one in which, after a reasonable length of time (4 to 6 months), it can be demonstrated that adhesions are preventing a satisfactory collapse of the lung, and recovery is doubtful with a continuation of the unsatisfactory pneumothorax. There must be an absence of any serious complication which would probably prevent the patient's recovery even if a satisfactory pneumothorax were established. The second requisite is that the pneumothorax cavity must be of sufficient size to permit one to manipulate the instruments. We wish however, to emphasize the point that the mere presence of adhesions is not an indication for operation.

With a maximum pneumothorax established, the pleura is examined with the thoracoscope. Under local or spinal anesthesia this is inserted in the middle or posterior axillary line and the condition of the lung, pleura, and the adhesions is carefully studied. The number of adhesions, their type and location, and the presence of lung tissue in them is determined. If they are found suitable for cutting, an electrode is introduced through the chest wall at that point which offers the most direct attack upon them. In the majority of instances the adhesions are back of the mid axillary line, therefore an approach from the anterior axillary or the mid clavicular line is frequently adopted. The penetration of the electrode through the pleura is observed through the thoracoscope and the adhesions are still further studied. They are then picked up and thoroughly coagulated and finally divided with the cutting current. By this careful procedure the larger blood vessels are avoided and the smaller ones present in the adhesions are coagulated before division, the presence of lung tissue in the adhesions is noted and the

line of division placed well beyond, and existing tubercles are seen and avoided. Provided the lung itself is not damaged the risk of pyogenic infection is almost nil and the chance of hemorrhage reduced to a minimum. A fluid reaction in the pleura may or may not occur. When it does, it is usually serous and absorbs readily, although rarely thick tuberculous pus may appear. If it is impossible to section completely the adhesion or adhesions at one sitting, they may be coagulated beyond the point of section. Then, if they do not stretch and thin out through the coagulated zone, a second pneumolysis may be undertaken later. From the figures at hand about 65 per cent of all suitable cases have their cavities closed and lose their positive sputum following internal pneumolysis for adhesions.

Apicolysis

In occasional instances when the lung is adherent and there is a localized cavity at the apex, the operation of plombage, extrapleural pneumolysis, or apicolysis is indicated. This should be reserved for those patients who are too sick for a localized thoracoplasty and in whom a phrenic interruption and scaleniotomy have failed. The operation has had its swings of popularity and regression; it cannot be warmly recommended because it is unsurgical in principle in that it creates a large dead space necessitating a foreign body plomb. Either the anterior or posterior approach may be used, the latter is preferable. A small portion of the second rib anteriorly or of the third or fourth posteriorly is removed subperiosteally, the periosteal bed is split and a line of cleavage established between the endothoracic fascia and parietal pleura. With the finger the parietal pleura and underlying lung are then carefully dissected free from the overlying ribs, the base of the neck, and the mediastinum. This free portion of lung and pleura is then displaced downward and the cavity filled with the plomb, which is usually paraffin, but may be muscle or fat, or vegetable fat. The muscles are carefully sutured and the skin closed without drainage. The disadvantages of the plombage operation are obvious: there is the presence of the large foreign body with its

dangers of infection, erosion into the lung or pleural cavity, or its eventual extrusion externally, and furthermore its presence hinders accurate roentgen ray examination of that portion of the lung.

The Phrenic Nerve

The subject of phrenic nerve interruption presents too large a subject to be discussed adequately in this short presentation. First proposed by Stuertz in 1911, the procedure was almost ignored until 1922. It then became increasingly popular until relatively recently when some of the enthusiasm for it as an easy panacea for unilateral tuberculosis seems to have abated. The operation itself is so simple that considerable harm has been done by its performance by those who have advocated and made use of it as a means to a quick cure, at the same time forgetting or failing to understand the essential principles underlying the treatment of pulmonary tuberculosis. Phrenic interruption may be either permanent or temporary. If the former is desired, the nerve is avulsed (phrenic exeresis) or carefully resected together with its accessory branches and the nerve to the subclavius. Until 1932 permanent phrenicectomy was almost universally advised. Since then, however, due in part to an excellent paper by Barnwell, temporary phrenic interruption by crushing or section and suture has been the operation of choice in most instances. This produces a paralysis of the hemidiaphragm for 6 to 10 months, which may be all that is required. If this proves beneficial, the paralysis can always be made permanent; if, on the other hand, the desired result with closure of the cavity has not occurred, no futile permanent impairment of function will have resulted and in case of spread of the disease to the contralateral lung adequate treatment of the new lesion will not be hampered.

The problem of phrenic interruption has still another dual approach. On the theory that if rest is the ideal treatment for tuberculosis, still further rest may be assured by paralysis of the diaphragm. Quite true, and I have no criticism of this hypothesis. But somewhat over 80 per cent of patients with minimal lesions become completely arrested with rest alone; therefore we have not deemed it

wise or necessary to suggest phrenicotomy or phrenicopraxis immediately any more than we would urge artificial pneumothorax in every such instance. Rather, we have looked upon it as a procedure to be advised for more specific indications, usually if one or more cavities are present. Indications for phrenic nerve interruption, therefore, may be listed as follows:

(1) In cases where artificial pneumothorax is impossible.

(2) In cases where the artificial pneumothorax is incomplete due to the presence of adhesions; e.g.: (a) those cases in which the adhesions are extensive and not suitable for division; and (b) those cases where the lung is adherent at apex and base and a bow-string mechanism is produced and accentuated by the pneumothorax. Here relaxation and rise of the diaphragm may be most beneficial.

(3) In cases where artificial pneumothorax has been associated with unduly sharp reactions.

(4) In artificial pneumothorax cases where obliteration of the pneumothorax is occurring, or when discomfort occurs with the required refills; e.g.: in those cases where continued positive pressure seems undesirable.

(5) In artificial pneumothorax cases when treatment is completed and the pneumothorax is to be abandoned; e.g.: (a) as a preventive against too rapid expansion and resumption of function; and (b) when the lung fails to reexpand properly and symptoms of mediastinal drag appear.

(6) As a method of election in properly selected cases, hoping it will suffice.

(7) In conjunction with artificial pneumothorax on the same or contralateral side as an aid to the pneumothorax and when bilateral pneumothorax is contraindicated or unsatisfactory.

(8) Sometimes for hemorrhage when artificial pneumothorax is impossible.

(9) As a test procedure if the patient is a borderline case and localized thoracoplasty is considered to be too much of an attack at that time.

side a complete thoracoplasty is rendered less effective because of the rise of the liver, which prevents a maximum collapse of the ribs. (3) We have no control over the amount of lung collapsed; hence the collapse may be greatest of the normal lung tissue, which we should like to conserve.

It is extremely difficult to determine beforehand when phrenic interruption will prove successful or even beneficial. Were we able to prognosticate the result with any degree of accuracy, much of our contemporary discussion as to the pros and cons of the operation would be eliminated. The action and interaction of the several forces involved must be considered in every case, and for this purpose fluoroscopic study is most helpful. No general rules can be laid down. We know that, left to itself, due to the presence of its elastic fibres and smooth muscle the normal lung tends to contract concentrically about its center of gravity. In the normal chest two forces alternately prevent and favor this; the up and down pull of the diaphragm and scalene muscles, and the inward and outward thrust of the chest wall. Furthermore these two forces do not act homogeneously on all portions of the lungs; that of the ribs varies at different levels, while the effects of the pull of the diaphragm vary not only in the long axis of the lung but also in the anteroposterior diameter because of the fact that the anterior tendinous portion rises much less than the posterior muscular part. In disease further alteration of these factors is caused; *first*, by the destruction of larger or smaller areas of the normal lung and the appearance here of fibrous tissue of repair, which may either contract or retract; *second*, there may be adhesions between the lung and chest wall or mediastinum; and *third*, the diaphragm may be fixed. Hence it is essential to understand as accurately as possible the mechanics and pathology within the chest before hazarding a prognosis as to what will happen in any given case after paralysis of the hemidiaphragm. One can be much more optimistic in the presence of a thin walled, small or moderate sized cavity in the posterior or mid-portion of the lung somewhere below the clavicle, with relatively little surrounding infiltration, a free diaphragm and only delicate

We do not advise phrenic interruption as a routine preliminary to extrapleural thoracoplasty for three reasons. (1) Frequently it renders cough more difficult and ineffectual and thus favors stagnation and spread of secretions and so makes convalescence more difficult and prolonged. (2) Particularly on the right

surface adhesions than where the cavity lies anteriorly in the midst of dense scar tissue, with a thick wall of its own and with a fixed diaphragm and an extensive adhesive pleuritis. In this type of case, phrenicectomy is a waste of time offering nothing to the patient but added pain and unjustifiable hope.

During the past five years division of the scalene muscles has been suggested independently of or as an adjunct to phrenicectomy. The operation is theoretically sound and should, I believe, always be combined with phrenicectomy for lesions in the upper half of the upper lobe. It is not difficult technically although care must be taken to avoid the brachial plexus and long thoracic nerve and the great vessels.

What results are to be expected following phrenic interruption? In a series of 500 cases O'Brien reported 50 per cent cavities closed. Graham reports 9 per cent cures by phrenicectomy alone and Alexander about 20 per cent. Most of the other reported series give 10 to 25 per cent of cures. In the realm of "improved," so much personal equation and variation enters that it leaves one bewildered as to what to think. The risk of the operation, while slight, is not entirely negligible. About 1.2 per cent will present some complication directly attributable to the operation and there is an operative mortality of about 0.5 per cent. The operation, however, has an important place in the treatment of pulmonary tuberculosis and with careful selection of cases one can confidently anticipate that the cures will rise and the disappointments recede.

Extrapleural Thoracoplasty

Finally we arrive at extrapleural thoracoplasty. This is not always undertaken, however, only after lesser measures have failed, but is sometimes the initial surgery of election. By extrapleural thoracoplasty we mean the subperiosteal removal of portions of several ribs without entering the pleura; thus the operative procedure does not involve the lung itself, but is carried out entirely in the normal tissues of the chest wall. In this manner that part of the bony cage of the chest which overlies the tuberculous pulmonary lesion is removed and collapse of the underlying lung thus liberated is pro-

moted by: *first*, the intrinsic tendency of the lung to contract due to its normal contractile tissue and also the fibrous scar tissue present; *second*, by the extrinsic factor of atmospheric pressure. The resected ribs drop downward and inward with a resultant collapse in these two dimensions. Regeneration of the resected portion of the ribs occurs fairly rapidly from the periosteum that has been left so that within a month a bony cuirass has begun to form. This is an essential feature of the operation for it is in this fashion that the collapse is maintained and respiratory movement in the underlying lung greatly diminished or abolished. Through the surgical application of collapse and rest, therefore, we come back to the first precept in the treatment of pulmonary tuberculosis—*maximum rest*.

The operation itself has undergone considerable change and development since its inception by deCernville in 1885. In great measure because of the work of Brauer and Friederich, and Sauerbruch our present paravertebral thoracoplasty has evolved, for they demonstrated that the most effective collapse of the greatest amount of lung tissue was brought about by a paravertebral resection of the ribs from their junction with the transverse processes of the vertebrae to beyond their angles. Modifications such as more extensive resection of the ribs and inclusion of the transverse processes themselves at times have been made but the basic principle of the operation remains as described by them. At present we feel that for upper lobe lesions the first rib to beyond the scalene tubercle, almost the entire second, and the third rib to the midclavicular line or beyond should be removed. Frequently, also, an apicolysis may be judiciously combined with the apical thoracoplasty at this time. Increasingly smaller proportionate segments of the remaining ribs need be resected ordinarily although in large basal or centrally placed cavities greater lengths of ribs must be removed over the site of the lesions, and in empyema it may be necessary to remove all of the ribs to their cartilages or even to their sternal attachments. Formerly the operation was done in one or two stages with resection of 9 to 11 ribs. Now it is always performed in multiple stages, at least two.

and frequently more. Furthermore, where-as we used to try to insist on a complete thoracoplasty in every case, we have found that this is not necessary, for, if a sufficient length of each rib is removed, in many instances a limited or regional thoracoplasty may be all that is required. The current practice, therefore, is to conserve as much good lung as possible by a more direct and extensive attack over the lesion itself.

When is extrapleural thoracoplasty indicated? The ideal patient is one with a unilateral chronic productive lesion who presents no symptoms of toxemia (i.e. with temperature below 100° F. and maintaining or gaining weight), without signs of tuberculosis elsewhere, and who has shown marked evidence of healing the pulmonary lesion as indicated by considerable fibrosis with retraction of the trachea to the affected side, elevation of the diaphragm, narrowing of the intercostal spaces, and supra- and infraclavicular retraction. Here we have a picture of the good chronic, so well emphasized by Archibald. This patient has already been under a careful and prolonged medical regimen and has accomplished all that is possible, but still has one or more open cavities with *persisting positive sputum or hemoptyses*. Without further help he is condemned to chronic invalidism and is a constant source of danger both to himself and others. Pneumothorax has proved ineffectual and phrenicectomy is useless because of the extensive adhesions, the already elevated diaphragm, and the density of the scar tissue and cavity walls. It is such cases that offer the best chance of success through thoracoplasty with closure of the cavities and disappearance of tubercle bacilli from the sputum.

Other indications for thoracoplasty are:

- (1) The presence of a solitary large cavity which has failed to respond to the less radical methods of treatment;
- (2) recurring frequent hemoptyses in the presence of negative sputum, which have failed to respond to simpler measures;
- (3) the occasional case that has severe pneumothorax reactions in whom phrenicectomy and rest have failed;
- (4) cases of tuberculous empyema following pneumothorax in whom the fluid persists and fails to resorb;
- (5) cases of spontaneous pneumothorax in whom the broncho-

pleural fistula fails to close and before a mixed infection occurs; (6) cases which fail to reexpand after the termination of pneumothorax therapy; (7) cases of tuberculosis empyema that have become secondarily infected with pyogens; (8) in certain bilateral lesions thoroughly stabilized and only after extremely careful selection. In all of these instances, however, there must have been evidence of stabilization or repair. Lacking this, even if the lesion be entirely unilateral, thoracoplasty will merely activate an already soft lesion, spread the disease, and result disastrously.

Besides the presence of a soft progressive lesion and toxemia there are other contraindications to the operation: the existence of cardiac or renal impairment, a low vital capacity and reserve air, while persistent dyspnea following phrenicectomy demands extreme caution. Patients over 50 do not as a rule respond well, and especial care should be taken with them. Tuberculosis elsewhere, as in the larynx, mouth, intestines, bones, or kidneys, is not of itself a contraindication, but thoracoplasty should be deferred until such lesions are under control; then it may prove most beneficial. Likewise hemoptysis is not a contraindication, conversely it is frequently a distinct indication. Each case must be considered on its own merits in light of the above. Dyspnea may be due to mediastinal retraction, and in such instances is an indication for the operation.

If the above recommendations are adhered to there will still remain an operative mortality of from 5 per cent to 13 per cent, depending largely upon the care with which the selection is made. In certain institutions where the facilities for postoperative care are not of the very best and where there is a high incidence of wound infections this mortality will be even greater.

By a cure is meant closure of the cavity and rendering the sputum negative on repeated concentration examinations. Either may occasionally result independently of the other and here the final verdict must be held in abeyance. Patience is required and provided the operation has been properly performed, such patients should be allowed eight or ten months further on a strict medical regi-

men before considering further surgery, for I have not infrequently seen a perfect and permanent result follow such an interval when in the early postoperative period it seemed as though failure were inevitable, and indeed it would have been had not strict rest and very carefully regulated exercise been insisted upon. The result is a well and most grateful patient who has been saved the risks of further and somewhat difficult surgery. About 35 per cent of all cases operated upon in the past have been rendered sputum negative and have been returned to an economically useful life. Some of the women have borne children without exacerbation of their disease, and men and women have resumed arduous occupations of manual labor. The tendency is toward a betterment of the above figure. For two years O'Brien has had over 80 per cent "cures," and in one of our institutions last year out of a series of 22 completed cases 80 per cent obtained negative sputum reports. In another group of 21 cases operated upon by me at two institutions this past winter 58 per cent have already become sputum negative with closure of their cavities. In this group there were two deaths—one following violent exertion and emotional stress a few hours postoperative due to acute cardiac dilatation, and the second at the end of the third week postoperative due to a progressive myocardial failure. It is fair to assert that we should expect a 65 to 70 per cent "cure." Furthermore, in evaluating these results one must bear in mind that of this group, without thoracoplasty, few if any would ever have been able to return to a normal or economically useful life.

The above enumerated procedures have so far been considered separately. All may be combined in various ways either unilaterally or bilaterally depending upon the lesions present and their response or lack of response to the therapy applied.

There is one further side to surgery as an aid in treating pulmonary tuberculosis to which but scant attention has been paid heretofore but which must assume a more prominent position in the future. That is the economic aspect. As physicians we owe a duty not only to the pa-

tient but to his family and also to our fellow men. It is our duty to cure the patient in the shortest possible time, thereby reducing his period of infectiousness to a minimum and also keeping the cost of care of him and his family as public charges at the lowest possible figure. With the burden upon our public institutions and welfare rolls becoming increasingly acute and with the spread of sickness and health insurance, the task of keeping the population well and restoring the sick to health and ability to work is placed squarely upon the shoulders of the medical profession.

I need cite but one instance. A man of 42 had had tuberculosis for 21 years and had passed most of those years as an inmate of a government hospital because of his positive sputum and frequent hemoptyses. During this time he had not only been unable to contribute anything but on the other hand was a public charge. Even at \$1 a day this amounts to \$7,300. At present the cost per hospital day is approximately \$4 per patient; hence we have indirectly contributed about \$25,000 toward his maintenance. Following extrapleural thoracoplasty his cavities were closed and he became sputum negative within three months, all of which could have been accomplished at least 15 years before at a saving of \$18,000 to the public.

If therefore physicians and surgeons believe that surgery is a help in the treatment of certain types of pulmonary tuberculosis, as we know it is, it is our cogent duty to urge its adoption with utmost earnestness in all suitable cases. In this way the patient will be restored to a gainful life more promptly, the spread of the disease among others will be retarded, and the public load will be lessened. Surgery will effect no magical cures nor will it in any way supersede a careful medical regimen, but it will shorten this markedly in some instances, and in others, where such measures have failed, its adoption will effect a cure and restore to normal life a group of patients, who, without its help would be condemned to chronic invalidism and remain a constant menace to their families and friends.

768 PARK AVENUE

CHRONIC ILLNESS DUE TO DIETARY DEFICIENCY

MORRIS L. DRAZIN, M D, *New York City*

The literature is replete with experimental and clinical evidence indicating the importance of diet as an etiologic factor in the production of disease. The genesis of such definite deficiency disorders as xerophthalmia, beriberi, scurvy, pellagra, and rickets by a deficient diet is too well known to require elaboration. Of far greater importance is the recognition of the fact, which has been emphasized by students of the problem, that many obscure disorders are in reality manifestations of chronic nutritional deficiencies.

The association of infection with scurvy was pointed out by Hess¹ who showed that such infections as furunculosis, grip, and nasal diphtheria were exceedingly common in infants affected by scurvy. Conversely, it was found by Mettler, Minot and Townsend² that many people with an appearance of good health suffer from a lack of well-being because of a nutritional imbalance. In such people infections may precipitate symptoms of a typical deficiency syndrome, but more often, a chain of symptoms not definitely traceable to a deficiency disorder.

Moore and Brodie³ reported a case of an infant, dying from cerebral hemorrhage, who presented at postmortem changes typical of beriberi. The study of the mother's diet during her pregnancy revealed that she subsisted on a markedly deficient diet.

Barnet Sure⁴ reported that nursing young of the albino rat require approximately a hundred times as much vitamin B in the form of dehydrated yeast as vitamins A and D furnished by cod liver oil during the lactating period and suggested that gastrointestinal disturbances in infants are due to a deficiency of vitamin B in the diet of the lactating mother. This deficient diet is the typical American diet composed of degerminated cereals, sugar and meat. This was recently corroborated by the very interesting work of Elsom⁵ who, in a carefully controlled experiment upon two humans, produced recognizable clinical symptoms corresponding in many respects to changes

described in vitamin B deficient animals. The diet of these two patients was adequate except for moderate limitation of vitamin B.

In the Orient, typical beriberi in breast fed infants whose mothers had been fed on polished rice is very common. This can be cured and prevented by adding vitamin B containing food (rice polishings) to the diet of the mother, or concentrated vitamin B to the diet of the infant.

Hoobler⁶ reported that mild forms of infantile beriberi are quite common in this country. The symptoms of this disorder—anorexia, loss of weight, spasticity of the arms and legs, rigidity of the neck, restlessness and fretfulness, pallor, low percentage of hemoglobin, and a plaintive whining cry—are readily alleviated by administration of sufficient vitamin B in the infant's diet.

Cody⁷ found that vitamin A is necessary to maintain the nutrition of the nasal and tracheal epithelia. He identified deficiency in vitamin B with a definite postnasal syndrome, consisting of a postnasal mucous discharge and smooth, moist, creamy-white and slightly thickened posterior tips of the middle turbinates.

Hess, Lewis and Barenberg¹⁰ concluded that the usual American diet is not deficient in vitamin A and that the addition of extra vitamin A does not add any immunity to infection. Yet they admit that a lack of vitamin A may occur as a result of vagaries of diet, or when absorption is defective, for example, in diarrhea and jaundice.

The relation of vitamin A to the prevention of respiratory infections is still unsettled.^{9, 10, 11, 19}

There is an accumulation of evidence that a deficiency in vitamin A may play a role in the formation of urinary calculi.^{12, 13, 14, 15} Vitamin A deficiency has also been connected with the production of various dermatoses. Loewenthal¹⁶ in studying prisoners in East Africa noticed that those suffering from night

blindness and xerophthalmia were affected by a clinical picture of acne vulgaris combined with a peculiar dermatosis. These patients subsisted on a deficient diet of maize, beans, dried meat, salt, and sweet potatoes. When one ounce of cod liver oil was added to their diet, the ocular and dermal symptoms cleared up. Although nutritional night blindness is rare in this country¹⁷ Jean and Zentmire found that 21 per cent of a group of children they tested had impaired adaptation to dark.¹⁸ Half of these children were retained for study and given a good diet including cod liver oil, and all of them regained normal adaptation to dark.

Clausen¹⁹ concludes that deficiency of vitamins A, C, and to some extent B, predisposes animals to infection. In man, loss of resistance to infection exists in outspoken deficiencies of vitamins A and C. It is also established that Rachitic infants have a greatly lowered resistance to pertussis. There is some evidence that a good diet during the early months of life will decrease the number of infections during the latter part of the first year and during the second year. But he adds that if the host is consuming an adequate diet, the addition of more vitamins will not increase resistance to infection.

The evidence cited emphasizes the fact pointed out by Sherman²⁰ that latent deficiency disease is a *real thing and not an imaginary concept*.

This article deals with a group of chronically ill patients observed in the outpatient department and the wards of the Mount Sinai Hospital. These patients have obscure ailments, present a multitude of complaints, and are often referred to by the doctors in the clinic as "chronic complainers." Their histories are often difficult to elicit and to evaluate. These patients pass from doctor to doctor, and from one clinic to another. They make numerous visits to the outpatient department, and are frequently put through extensive, elaborate and costly diagnostic procedures, for the most part with negative results. As a last resort they are sent to the Mental Health and Physiotherapy Departments, where prolonged sessions are without avail. This is because the basic underlying factor of a deficiency state has been overlooked.

On careful questioning these patients

give the following history: For some time past, often as far back as two years, or more, there has been increasing generalized nervousness and irritability; they have become easily upset and excited. They complain of distressing pains and aches in various parts of the body. The pains may be arthralgic, along the nerve trunks, or may assume a radicular distribution. Paresthesias, and tingling sensations of the fingers may be present. The patients invariably complain of fatigue, of inability to carry on their work, because of a sense of weakness. A generalized tenderness of the body and a tendency to bruise easily are outstanding complaints. They tell of frequent upper respiratory infections, of tender gums and bad teeth. The patients are usually constipated, their digestion is fitful, and their appetites are variable. There may be a history of moderate, and at times considerable weight loss. Often they call attention to edema of the ankles and feet.

A dietary history in all cases reveals that these patients have subsisted on a deficient diet for periods of one to three years and longer. Most of them are poor and are supported by charitable organizations and home relief. Their diets are usually composed of starches—bread, cereals, spaghetti, also olive oil, some butter, little, or no fruit, especially the citrus variety, and very few vegetables (most of them overcooked). These diets are low in protein and poor or even grossly deficient in vitamins.

Most of the patients under consideration are middle-aged. Females predominate in this series. The outstanding findings on physical examination are: (1) General pastiness and sallowness of complexion; (2) coated tongue—at times beefy red or smooth-edged; (3) carious teeth; (4) infected gums; (5) tenderness of various parts of the body, especially the calves of the legs and the interior margin of the tibiae and (6) ecchymotic spots on the skin—at times extensive.

Anemia is not often present. The blood platelets often are reduced in number. The blood chemistry findings are not markedly altered. The tourniquet test ($3\frac{1}{2}$ min. at 90 mm. of mercury) is frequently positive. Not uncommonly there is evidence of sinusitis and other upper respiratory infections. Frequently,

arteriosclerosis and hypertension are encountered as associated conditions

Therapy presented some difficulty, because the patients could not afford to procure the additional foods ordered. The cooperation of the social workers and the dietitians at the hospital was obtained and every effort was made to secure the needed funds. The daily diet was supplemented by the following foods: (1) a large can of irradiated evaporated milk or a pint of fresh milk, (2) the juice of six lemons or their equivalent in orange juice or grapefruit juice, (3) one-half pint of canned tomato juice, (4) whole wheat bread, (5) a liberal helping of meat, fish, cheese, and eggs and (6) cod liver oil, one ounce daily. In addition they were instructed to consume other foods that they were accustomed to take. Many of the patients who followed dietary directions showed a remarkable improvement in their physical and mental make-up. They gained weight and strength, and the tenderness of the body and calves disappeared.

Case Reports

Thus far we have observed twenty patients whose diets were grossly deficient for a long period of time. The accompanying table summarizes the symptomatology present in these patients.

The following four cases are reported in detail.

CASE 1 A C, age 29, white Italo American widow born in U.S. Admitted to Mt. Sinai Hospital O.P.D. Medical Clinic April 15, 1935. Her family history is irrelevant. She has had occasional colds. She underwent an appendectomy and uterine suspension 12 years ago. She had three normal deliveries 11, 7 and 5 years ago. Two miscarriages in the second month of gravidity occurred four and three years ago. The patient is living with her children, and is supported by the Emergency Home Relief. She was brought to the clinic by an investigator from the Home Relief Bureau because she was too weak to come to the clinic alone. She complained of pain in various parts of her body, weakness, fatigue and backache for the past five months. During the same period she noticed that she bruised easily, and that ecchymotic spots on her body would appear spontaneously. Her menses had become more frequent and profuse in the last four or five months. She had lost 10 pounds in 1½ months; her appetite had become

poor, and she vomited occasionally. Her bowels were regular, and there were no urinary, cardiovascular or respiratory complaints. Her sleep was poor, and she became easily excited.

Dietary history. For the past seven months the patient was forced to curtail her diet because of lack of income. She partook of one meal daily which consisted of spaghetti, some greens, and once or twice a week a little meat.

Physical examination showed a patient who was pale, of sallow complexion, and poorly nourished. Her pupils reacted to light and accommodation. Her teeth and gums were in poor condition, and the gums bled easily. Thyroid was small. The heart and lungs were normal. The abdomen was relaxed, and there was a moderate visceropertosis. She had varicose veins of the legs. Her knee jerks were active. There was a generalized tenderness of the muscles and bones of all extremities, especially the calves of the legs. An ecchymotic spot was present over the internal aspect of the left knee. A pelvic examination revealed a lacerated cervix, and a slightly enlarged uterus in anterior position. The rectal examination was negative. Her weight was 130 lbs.,

TABLE SHOWING SYMPTOMATOLOGY OF THE TWENTY PATIENTS OBSERVED. SYMPTOMS AND SIGNS ARRANGED IN THEIR ORDER OF FREQUENCY.

Symptom or sign	Number of patients in which it occurred
1 Deficient diet	20
2 Sallow complexion	20
3 Nervousness and irritability	19
4 Asthenia and fatigue	19
5 Generalized pain	18
6 Loss of weight	16
7 Constipation	16
8 Coated tongue	16
9 Generalized tenderness	15
10 Tender calves	14
11 Paresthesias	13
12 Frequent colds	12
*13 Carious teeth and gingivitis	11
14 Anorexia	10
15 Positive tourniquet test	10
16 Ecchymoses	9
17 Profuse menses	5
18 Pigmentation	3
19 Peripheral neuritis	1 doubtful 2

* Five additional patients were edentate. Of these 3 patients wore plates. Of the twenty patients 17 are female, 3 male. All are white. Sixteen patients were above 40. Twelve patients subsisted on a caloric intake of less than 1500 calories.

temp. 98.6, resp. 20, B.P. 120/80. Her urine was negative. Hemoglobin was 86 per cent; red blood cells, 5,400,000; leucocytes, 8250, of which the polynuclears were 68 per cent, lymphocytes 30 per cent, and mononuclears 2 per cent. Tourniquet test at 90 mm. of mercury, for four minutes was positive. The basal metabolic rate was plus 17 per cent. The diagnosis was dietary deficiency, eyestrain, and menorrhagia. She was given dietary advice, and was referred for refraction. Two weeks later she returned, distinctly worse, and stated that her diet had not been changed. The importance of supplementing her diet was impressed upon her, and the cooperation of the social worker was secured. She was told to consume daily, in addition to the food she was accustomed to take, the juice of six lemons or oranges, 1 can of tomato juice, 1 can of evaporated irradiated milk, $\frac{1}{2}$ lb. of meat daily, and two tablespoonfuls of cod liver oil.

When the patient returned two weeks later there was definite improvement. She felt and looked better. Her appetite was improved. She was stronger. Her bowels functioned better. There were no ecchymotic spots. She gained $2\frac{1}{2}$ lbs. The tourniquet test was faintly positive. On a subsequent visit two weeks later the improvement was found to have continued; the patient had resumed her housework. There were no further complaints of pain, nor was tenderness of calves present. The patient is still under observation.

CASE 2. R.G., white, 45 year old housewife, born in Austria. Her family history is irrelevant. She had had a long and checked previous history. She had typhoid fever 35 years ago, influenza 18 years ago. She had four pregnancies and one miscarriage. With the second and fourth pregnancy she developed eclampsia. In the past ten years she had been admitted 12 times to Mount Sinai Hospital, with the following diagnoses:

Sept. 28, 1925. Acute appendicitis. Appendectomy with drainage.

Apr. 27, 1926. Bicornate uterus. Excision of right horn of uterus, ligation of tubes.

Dec. 23, 1926. Postoperative ventral hernia. Ventral hernioplasty.

May 13, 1929. Cystocele, rectocele, cystitis cystica, anterior and posterior colporrhaphy.

Jan. 9, 1930. Chronic cystitis.

Feb. 4, 1930. Fissure in ano, external hemorrhoids, excision of fissure in ano. Hemorrhoidectomy.

July 22, 1930. Chronic cystitis, chronic pyelitis, solitary kidney (left).

Aug. 27, 1931. Psychasthenia.

Nov. 21, 1932. Asthma. Sensitive to duck and goose epithelium.

June 12, 1933. Chronic purulent sinusitis. Left sphenoidectomy.

Nov. 12, 1933. Psychoneurosis, bronchial asthma. Sigmoidoscopy.

The patient had attended practically every clinic in the O.P.D. of the Mount Sinai Hospital since 1925. Her visits to the surgical clinic dated from 1925, medical since 1926, gastrointestinal since 1926, ear, nose and throat since 1928, physiotherapy since 1927, gynecological and cystoscopic since 1933, eye since 1933, and skin since 1933. She attended many of these clinics simultaneously. During the past year she had numerous bladder irrigations, and many injections of adrenalin for her asthma. During the past few years she had noticed large and painful ecchymoses on her body. She had attacks of rectal and nasal bleeding, and her menses had become profuse during the same period. For the past two years she complained of constipation alternating with diarrhea, and backache. No limitation of motion was found in the spinal column. Complete gastrointestinal studies were negative. Her blood was essentially negative chemically, serologically, and hematologically. Repeated urologic studies both cystoscopic and roentgenologic showed that the function of her solitary kidney was good. In an attempt to arrest her bleeding tendencies she was given numerous injections of snake venom without success. When she came to our clinic on March 12, 1935, she complained of pains and aches everywhere in her body. She also complained of black and blue spots on body, bleeding gums, rectal bleeding, nasal bleeding, and menorrhagia. She stated that her body is very tender to touch, and that she suffers from attacks of asthma, frequent upper respiratory infections, and sinusitis. She also claimed to be so weak as to be unable to attend to her housework.

Physical examination showed a chronically ill, highly nervous female, weeping at the slightest provocation. The positive findings were generalized tenderness, especially of calves and shins, widespread, ecchymoses, lumbar spondylitis, and varicose veins of legs.

Her diet for more than two years was grossly inadequate. Her estimated average caloric intake was 800 calories. Her diet consisted of meat, fish, and cheese, each twice weekly; cooked vegetables once daily; very little, if any, fruit (practically none of citrus variety); bread, one slice with each meal; milk, very occasionally; coffee, three cups daily. Her blood pressure was 130 systolic, 80 diastolic, pulse 80-90, tourniquet test—4 minutes at 90 mm. of mercury was strongly positive. She was placed on a balanced diet and was especially urged to take large quantities of citrus fruit, and tomato

juice. It must be admitted that we did not expect to secure a therapeutic result in this patient. However, much to our surprise and satisfaction she returned on March 27, 1935, much improved. She felt stronger, and had fewer complaints. General aches and pains were less marked in spite of an acute ear infection which had to be incised.

On several follow-up visits, the latest June 28, 1935, patient continued improving. No ecchymoses for three months, although the snake venom injections were stopped in March. General tenderness had disappeared, there was no bleeding from the nose or rectum, and her menses were less profuse. The tourniquet test was very slightly positive. She had resumed her household duties. Mentally she is much more placid than formerly. She has been taking large amounts of fruit juices, but her protein intake is still low.

CASE 3 L E. This patient is a white female, 46 years of age, married, born in Russia. Her family history is irrelevant. She had typhoid at four years of age. She had no other illness except frequent colds, and complaints pertaining to her digestion and present illness. The patient has been married twenty-five years. Her husband is living and well. She has three children, 21, 16, and 14 years old. She had two abortions. Her menopause took place 14 years ago.

The patient came to the Mount Sinai Hospital O.P.D. in November 1926. She complained of epigastric distress, pain in R.U.Q. and arthralgias of phalangeal joints. At that time her physical examination was negative. Her blood pressure was 95/60, and blood urea 16 mg per 100 cc. The blood Wassermann test was negative. X-ray studies of her gall bladder and gastrointestinal tract were negative. She was referred to the neurological clinic in August 1928 where no organic cause for her complaint was disclosed, and a diagnosis of psychoneurosis was made.

She returned to the clinic in 1930 with complaints of pain all over her body and a feeling of being cold. Her physical examination was negative. Blood pressure was 150/60, and the Wassermann test was again negative.

She returned in February 1933 seeking relief for pain in the finger tips. The neurologist then found that she suffered from a peripheral neuritis of unknown etiology. At this time she had paresthesias and pain over her entire body, especially the extremities. Her ankle jerks were more diminished than her knee jerks. There were peripheral sensory disturbances in the extremities to all modalities. She stated that she lost 25 lbs. in six months. Her blood count showed

Hemoglobin, 98 per cent, red blood cells, 6,100,000, white blood cells, 10,500. The stained smear was normal. Her basal metabolic rate was plus 23 per cent. At that time her liver and spleen were not only found to be enlarged, but also ptosed. The liver was tender. Despite these findings the patient's complaints were considered to be functional. She was therefore referred to the physiotherapy department where she was treated on 50 separate visits between June 1933 and March 1934. As no improvement resulted the patient was sent to the medical clinic for an opinion. We saw this patient in December 1934, and left the following notation: "Patient has a multitude of complaints. She has pitting edema of the lower extremities. Diet utterly insufficient. Her complaints are due to chronic malnutrition. The tingling of the fingers is probably due to a vitamin B deficiency. A high caloric high vitamin diet was prescribed."

We did not see the patient again until June 1935. During the interval she was treated in the gastrointestinal clinic. There she was found to have an achlorhydria, however, following an injection of histamine, free HCL was secreted. X-ray examination of the stomach, duodenum, gall bladder, and spine were negative.

When the patient returned to our clinic, she again gave a history of weakness, fatigue, generalized pain and tenderness, paresthesias, especially in hands and feet, swelling of legs, feet and lower back, and a loss of 40 lbs in two years. All of her teeth had been removed and replaced by plates.

Her dietary history was as follows. Because of poverty she subsisted for the past four years on a very scanty diet. The calculated average caloric intake was about 1500 calories. The diet consisted of Meat, 1½ lbs for 5 persons twice weekly, fish, 1 lb for entire family of five twice weekly, 1 egg weekly, cheese once weekly, milk 2 glasses daily, bread, 1 slice, no vegetables, fruit once weekly.

Physical examination revealed a poorly nourished, sallow complexioned female. Her tongue was beefy and coated, heart and lungs were essentially normal, liver enlarged, ptosed, tender, spleen was palpable, there was pitting edema of the legs, feet, and over the sacrum, and no ascites. There was tenderness of the entire body, especially the calves. The skin of the dorsum of the hands was deeply pigmented, symmetrically and felt leathery. Neurological examination showed all deep reflexes depressed, left knee jerk less strong than right, left ankle jerk absent, right depressed, glove and stocking sensory dis-

turbances present for all modalities, vibration absent in hands and feet, position errors present in toes of right foot. Mentally, the patient was very irritable, and apprehensive. On the basis of the above findings the diagnosis of avitaminosis, possibly pellagra was made, and the patient hospitalized.

The patient upon admission to the hospital was placed on a high caloric, high vitamin diet, and gained 5 lbs. in two weeks. She looked and felt better. The tingling and paresthesias of her fingers decreased. The sacral edema disappeared, but the peripheral neuritis and edema of the legs were still present. It was then attempted to ascertain whether crystalline vitamin B would have any effect on the peripheral neuritis. Accordingly for a control period of three weeks she was placed on the regular ward diet, after which the vitamin B therapy was commenced. The patient lost weight and began to complain; her mental symptoms grew more pronounced, and she became irritable and unruly. The edema of the legs disappeared entirely, although the peripheral neuritis was not appreciably influenced. It was then planned to reinstitute the original high vitamin, high caloric diet, but the patient refused to remain in the hospital and left against advice.

CASE 4. S.G. is a 49 year old female born in Austria. Her family history is irrelevant. Her previous history was negative except for frequent colds. Her menses were regular till November 1934, but since that time they came at infrequent intervals. She had two children 16 and 13 years ago. She had no miscarriages. This patient is widowed and is receiving aid from various social agencies.

Her first visit to the O.P.D. of the Mount Sinai Hospital was in 1930. She complained of pains throughout her body, frequent colds, and swelling of her feet. Her physical examination was negative except for carious teeth and spongy gums. She weighed 119 lbs., her blood pressure was 140 systolic and 70 diastolic. She remained away from the clinic until June 1934.

She came to the gynecological clinic with a complaint of pruritis vulvae. She had a moderate cystoectocoele, a second degree uterine prolapse, and a small cervical polyp. Her uterus and adnexa were normal. Her urine was normal, and smears from urethra and cervix were negative. A biopsy from the cervical polyp showed a fibromyomatous tumor. She was under treatment in that department until October 1934. She then complained of pain in the lower spine and swelling of her feet.

Physical examination revealed a tender coccyx and edema of her legs and feet. Since her weight was 122 lbs. (ideal 100

lbs. for her height and age) it was thought that she should be placed on a reduction diet of 1000 calories. When her diet was investigated by the dietary instruction department of the clinic it was found that her diet was unsatisfactory, and a high vitamin moderately high caloric diet was ordered. For a time she followed this diet and improved considerably. However, because of home conditions she failed to adhere to the diet and returned to the medical clinic in March 1935 complaining of pain under the right scapula, spontaneous ecchymoses, and weakness. Physical examination showed a short, stocky, poorly nourished, middle-aged female. She had tender, necrotic, easily bleeding gums, carious teeth, scattered ecchymotic spots on body, and tenderness of muscles and calves. She also showed edema of legs and feet, and had a zone of hyperalgesia on the right side corresponding to the level of the sixth dorsal vertebra. The tourniquet test was positive. The blood pressure was 130 systolic and 90 diastolic. Her blood count showed: hemoglobin, 86 per cent; red cells, 5,040,000; white cells, 9250, of which the polynuclears were 69 per cent, lymphocytes 25 per cent, mononuclears 3 per cent, and eosinophiles 3 per cent; platelets, 195,000. X-ray of spine showed marked bony atrophy, and x-ray of chest revealed healed tuberculous foci, thickened pleura, and arteriosclerosis of heart and aorta. X-ray examination of long bones was normal. Blood calcium was 11.6 mgs., blood phosphorus was 3.6 mgs. per 100 c.c. Similar figures were obtained at a subsequent examination three months later.

A diagnosis of dietary deficiency was made. She was placed on a high vitamin, high protein diet. She was urged to consume large quantities of citrus fruit juices. On several follow-up visits from March to July 1935 the patient appeared to be much improved. Ecchymoses had disappeared, and she looked better. Tenderness of calves was still present, although less marked. The tourniquet test was still slightly positive. The patient is still under observation.

Discussion

The dietary deficiencies presented by these patients are probably multiple. McCollum and Simmonds²¹ state that it is doubtful whether a deficiency disease ever occurs uncomplicated in man or animals. When the list of foods available is greatly restricted, and the diet made unsatisfactory to a pronounced degree the pathological condition produced is a complicated one. The same view is expressed by Cowgill and Hess,²¹ and Mackie.²²

Thus the tendency to edema may be due to a protein deficiency. The neuritic symptoms and generalized tenderness are in all probability due to a vitamin B deficiency.^{21 22 23 24}

The tendency to ecchymoses and the generalized tenderness is probably related to a vitamin C deficiency. However, some proof was recently advanced that vitamin B deficiency may produce ecchymoses.⁶ Hess,²⁵ Wright,²⁶ G Dalldorf,²⁷ and G Dalldorf and Russell²⁸ reported that increased capillary fragility is one of the signs of vitamin C deficiency. The tendency to upper respiratory infections may be influenced by a shortage of vitamins A and C.^{27 19 25 30} It is also fair to assume that because of the low protein intake a relative shortage of vitamin G also exists in some of these patients.^{30 31} The same probably applies to vitamin D. One should also take into consideration that grossly deficient diets lead to disorders due to lack of such vital minerals as calcium and certain important amino acids.³²

Comment

It will be noted that several of our patients were psychoneurotic. The anamnesis and physical findings should be examined in this type of individual with special attention to the possibility of dietary deficiencies. Their multiplicity of complaints often persuades them to eliminate essential foods from their diets.^{31 33 34 35}

The problem considered in this paper is important not only from the diagnostic and therapeutic viewpoint as far as the individual patient is concerned, but it also has widespread sociological implications. With over 20 million people in this country on relief, the possibility of deficiency states developing because of insufficient

diet must be kept in mind. When a deficiency does develop, the most vulnerable—the very young, and the persons past middle age—are affected first. The seriousness of the problem from a public health standpoint is appreciated by all students of the question. This was recently emphasized by J S McLester in his Presidential Address before the American Medical Association.²⁹

Summary

1 Chronic illness due to dietary deficiency is discussed.

2 A dietary deficiency should be suspected in any case presenting the following symptomatology:

- (a) Asthenia and fatigue
- (b) Nervousness and irritability
- (c) Generalized tenderness, especially of calves
- (d) Paresthesias
- (e) Dental caries and gingivitis
- (f) Coated, beefy, red, or smooth tongue
- (g) Increased capillary permeability.
- (h) Constipation
- (i) Frequent upper respiratory infections
- (j) In more advanced cases—anorexia, vomiting, edema, peripheral nerve changes, and pigmentation of skin
- (k) History of a faulty or inadequate diet

3 Evidence is presented that the symptoms complex described is probably due to multiple deficiency.

4 The sociological, Public Health and medical aspects of dietary deficiencies are indicated.

5 A simple plan for supplementary dietotherapy is suggested. The daily diet of the patient should be enriched with fruit juices, milk, whole wheat bread, meat, fish, cheese, eggs, and cod liver oil.

PIPES, NOT CIGARETTES, CAUSE MOST TOBACCO BLINDNESS

A good word for cigarettes and a bad one for pipe smoking, as causes of the dimness of sight due to tobacco poisoning of the eye's nerve cells and called tobacco amblyopia, were reported by Dr. H. M. Traquair of the Royal Infirmary of Edinburgh, Scotland, at a recent meeting of the Medico-Chirurgical Society in that city, says Dr. E. E. Free in *The Week's Science*. During the past 22 years the Royal Infirmary has treated 1856 cases of this tobacco blindness, the first symptom of which often is failure to recognize friends on the street, followed by a slow increase of what seems to be a continual mist in front of the eyes. Only eight of all the patients treated were women. Nearly all of the men were either pipe smokers, snuff users or persons who chewed tobacco instead of smoking it. As small an amount of tobacco as half an ounce a week can cause this tobacco blindness, although the usual dose necessary to cause trouble is about three ounces of pipe tobacco every

week for a considerable time. In one especially susceptible individual, smoking only ten cigarettes a day caused the eye difficulty but the total number of cigarette smokers affected was extremely small. Dr. Traquair finds that excessive use of cigarettes is likely to damage the heart or the digestion and thus force the victim to stop smoking before there are noticeable effects on the eyes. Among pipe smokers and snuff takers it is the eye trouble which usually happens first. Fortunately the tobacco blindness is curable after a few weeks by stopping all use of tobacco. Just why pipe smoking should affect the eyes while cigarette smoking strikes at the heart or stomach Dr. Traquair was unable to say.

In some European countries medical graduates are required to practice several years in the rural districts before settling in the towns of their choice, in order to remedy the scarcity of rural physicians.

OBSERVATIONS ON TREATMENT OF MENTAL DISORDERS IN SMALL GROUPS

EUGENE N. BOUDREAU, M.D., *Syracuse*

The great war opened up greater opportunities and then created a wider acceptance of psychiatry. Many men trained in this field, the author included, chose to enter the private practice of this special field in medicine after the war. It soon became evident to us that in meeting the problems presented, resources of many kinds must be called upon. Certainly no one brand or school of psychiatric thought was adequate to meet all demands, and certainly these demands were of varieties not met with intramurally. The greater number of our patients were not in need of hospital care. It might be that general medical survey with correction of defects there, plus a rapid survey and interpretation of their psychiatric or their psychological strains gave rapid relief. In a certain proportion, however, it was soon found necessary to have a place or places to which to remove them from the home environment in order to get temporarily for them the factors, or perhaps better, the control of the factors necessary for their proper care. It has, of course, been long known that isolation from the home environment is beneficial, but we are not satisfied in this era to stop at that. General hospitals are not usually equipped for the special needs in these cases, nor do they desire to receive such problems.

It became necessary, therefore, to develop or support the development of nursing homes. Here though the regime, the medication, and to a certain extent, the proper attitude towards such patients could be attained, it was found most difficult to secure such personnel and such activities for them as was most desirable. After nine years and many discouraging and even heart-breaking experiences in the struggle to attain ideals of care that seemed worthy, it eventually became imperative to develop a unit where full control over all factors was in my own hands.

By now it has become my strong belief

that in addition to the personal application of the psychotherapeutic methods of the day, that such persons as need treatment should be surrounded by nurses with personality background of culture and refinement, plus special training in psychiatric nursing and approach. Moreover, a proper atmosphere is considered to be an important condition. And by atmosphere, I believe we should mean comfortable physical surroundings, dignity of personal relation, sincerity, friendliness, and freedom from casualness and from too much institutional formality or evidence of the machinery of organization—in other words, an atmosphere where the individual has preserved for him, his self-respect, his sense of security, and his identity.

It took several years to acquire all of these requirements which were attained only by long hours of application to the problem.

At this point I will digress long enough to assert that there could, of course, be no excuse for enumerating these personal beliefs and experiences except to give the setting and background for the thesis I wish to present. To develop this I present briefly a few cases selected from our files.* From these records I hope to draw some justifiable conclusion that can have a wider application than thus far indicated.

Also, in explanation, these cases were selected from no period of our experience, nor for any particular type, but to attempt to show a cross section of our experience of six years in the application of the principles of care heretofore enumerated. Furthermore, these cases come largely from the every-day walks of life, and many are of the social status of the average of our public hospitals. However, the individuals were often admitted because of indications of moderate types of

* Twin Elms, Syracuse, New York.

*Read at the Annual Meeting of the Medical Society of the State of New York,
Albany, May 15, 1935*

disorder. In some instances we admit from the home cases on the admonitions of the families who might wish to try to avoid accepting or resorting to public care, and we can scarcely condemn the attitude of self-respect and independence thus exemplified. However, we must not support the feeling of stigmatization that so often attaches to public care. Then there is certainly another side from the family point of view. This is the desire to be near and to give their loved ones the various refinements of personal individual service not possible in the mass care in public hospitals. I do not mean, of course, harmful indulgences, for I have no sympathy with such, nor do I feel that the other extreme is justified. Yet in our scientific zeal, should we be unmindful of the tragedy of shattered hopes which mental sickness so often implies and the need for those concerned to gradually accept the certainty of a hopeless disorder? Other sources of our cases are the local Psychopathic Hospital and even a few from state hospitals.

Now let me present illustrative cases:

Case I. E. L., 22, English Jewess, shop girl. Admitted June 20, 1931, from Syracuse Psychopathic Hospital because she was a deportable alien. Relatives wished to avoid this and to allow her recovery and then return to her mother in London. Overactive, overproductive, variable delusional content. This continued slowly moderating for one week and by that time she was quiet enough to walk around the grounds and to be on the street in two weeks. July 17th was working 4½ hours in the occupational studio, though somewhat elevated in mood occasionally. Discharged July 27. Residence 35 days. Total illness 60 days. August 22, 1931, sailed for England unaccompanied.

Case II. M. L. W., 20, married, housewife. Admitted March 24, 1932, from Syracuse Psychopathic Hospital. One mild previous attack February, 1930. Overproductive, overactive. Delusional content. Rather childish, immature type; steady improvement with packs and sedative baths. Sixth day she was mingling with other patients. On the 7th day she started occupational work in the studio. Frequently disturbed after family visits. Occasional outbursts at other times. By May 4th she had improved so as to try two days at home. On return showed good behavior. Discharged May 7. 44 days residence. 51 days illness.

Case III. A. O'M., 45, single, music

teacher. Admitted at Syracuse Psychopathic Hospital March 4, 1932. Onset three months previously. At that hospital she was restless, noisy, moaning, wailing, resisted care and would lie on floor, constantly productive, nihilistic trend, no insight. Commitment to state hospital advised. Family decided to try a private hospital. Admitted March 29, 1932. Quiet, cooperative on arrival; dejected, "weepy." On April 4, she began working in occupational studio. Some further delusional ideas expressed April 27. Showed remarkable change the next week. Dejected demeanor gone. Later some swing to lower mood. Occasional period with delusional content. After successful visits home and to relatives, she was discharged June 6, 1932. 68 days residence. Total illness period 158 days.

Case IV. D. S. G., 68, widow. Admitted from her home on physician's certificate, January 25, 1933. She had been well up to the previous November. She began to be tired at Christmas time. Sleepless. January 15, began to be fearful, thoughts of poverty, of having contracted debts she could not pay. The state troopers would apprehend her, drew shades. Retinal arterio-sclerosis. B. P. 180/90. Enlarged heart. Leaking valves. Slight edema along tibiae. She had continued fears; feelings of fear of vague harm, some confusion at times. Slow improvement until she had regained clearness and confidence. Most fears gone. Went home with companion July 7.

Case V. V. D., 20, single, student. Admitted April 21, 1933. Overactive, pert, sleepless, under much pressure, rapid improvement. Not fully recovered, slight insight but on insistence of mother discharged to her care May 12. Did well and seemed normal for two days. Mother developed tonsillitis. Then she became overactive again and returned May 16. She made steady, slow improvement. However, there appeared some bizarre, delusional ideas of sex coloring—belief of pregnancy—of having been married to a college student, H. S., but there had been no physical contact. "God did it." This was transitory and by July 30, she was fully recovered. Residence 100 days. Period of illness same.

Case VI. P. V. C., 26, social worker, college graduate. Admitted May 1, 1934. A previous attack in 1930 while in Harvard. At Boston Psychopathic. Diagnosis: Catatonic Dementia Praecox. Recovered. Continued graduate studies. Took a position as a social worker with T.E.R.A. Winter of 1934 became restless and had some phantasies. Could not rest, went home to another city. There family was advised to have him

admitted to a state hospital There he was quite inaccessible after the first interview Reported to have ideas of reference and to have taken fixed postures Discharged May 1, 1934 Diagnosis D P Catatonic Unimproved Admitted to Twin Elms, May 1, 1934 Showed an expansive state, talkative, dramatic, reciting poetry Very distractible overproductive, resentful towards family for taking him to state hospital later refused to wear his clothes until he had cut off the name tags which the hospital had sewed on Rapid recovery supervened Confidence obtained He ventilated his difficulties easily and readily Discharged May 29, 1934 Residence 29 days Length of illness 79 days Well and working today

Case VII A M F, 20, single, Italian parentage, normal school graduate Admitted June 15, 1934, from her home Mild manic state Rapid recovery with pricks, and neutral baths Psychological ventilation here also was complete Discharged July 20, 1934 Residence 36 days Illness 38 days

Case VIII F C L, jr 27, unemployed Admitted June 21, 1934, from Syracuse Psychopathic Hospital with a diagnosis of Dementia Praecox, paranoid type Oldest of four father a business man Four years at Hobart College Two upsets while at college—January 1930, and again just before midyears, 1931, and was not given a diploma On admission it was found that the onset of the disorder had followed a series of discouragements and an altercation with his father Left home and wandered away At the Psychopathic Hospital he was unproductive, antagonistic, indifferent simple, silly, and had a sense of unreality The family was advised to commit him to a state hospital At Twin Elms he was slow in response and conscious of it Blamed his difficulties upon somatic state, teeth, jaws, sinuses On defensive Blamed the noise at Syracuse Psychopathic Hospital the hard beds (?), the ignorance of the attendants kept him under tension After two days ceased to make somatic complaints and began entering upon the activities arranged Cooperative By July 6 given parole His car was sent to him Full ventilation of his conflicts Discharged July 24, 1934 after a formulation of the situation was given to patient in presence of his parents Residence 34 days Illness 69 days

Case IX E G, 24, single, stenographer and musician Early life uneventful Finished high school at 16 Entered Syracuse University Left because of pneumonia Never returned Took a business course Worked as a stenographer and bookkeeper In the meantime showed exceptional talent

in music Sponsored by a local musical organization for a year's study in New York City The onset of illness thwarted this plan In temperament described as even-tempered and good natured Oversensitive Neither sociable nor seclusive until the last year No love affairs, though popular with boys In November, 1932, the disorder followed fears of losing her position it was said Began to have somatic complaints without medical substantiation Then depression somatic delusional trend, seclusiveness, ideas of influence, disinclination to exert Admitted to Syracuse Psychopathic Hospital, March 15, 1933 Transferred to Marcy State Hospital, June 10, 1933 with a diagnosis of Dementia Praecox, catatonic type There she went through a long period of stupor, i.e., standing long intervals at her bedside, required total care and spoon feeding Following that the hospital notes were as follows "July 14, 1933—receives sodium amylal treatment Slight temporary improvement July 29, 1933—returned from a parole lasting only a few days which satisfied the parents she could not be cared for at home" The later notes all indicated she remained in a "mute, catatonic, resistive, uncooperative" state "January 6, 1935—Catatonic, resistive, no improvement" Transferred to Twin Elms, February 3, 1935 There has gradually supervened after being here steady improvement in behavior, first she began to care for natural functions, then to dress and adorn herself, stopped eating with her hands and fingers and secreting food in bed Gradually after steady effort takes daily baths herself Facial expression has become entirely responsive to situations She smiles, is alert to everything that goes on, and is very curious She assists nurses with routine work She has at intervals returned to her violin and has executed strikingly well However, her interest in this has not revived to former level At times she speaks briefly, more times she whispers under her breath or gestures her responses Still she rarely sits down refuses to wear shoes for days at a time strongly desires to leave the house but when she gets outside there appears blocking or negativistic reaction, though on the first occasion she walked about the grounds occupational studio etc She has now been paroled to her home with a well selected companion to find the full possibilities of convalescence

By these brief but concrete stories, I believe there can have been conveyed to you something of the reality of the benefits to these sick, which we have seen with our own eyes, of those factors earlier referred to There can be no doubt that in

the fluid state of an early psychosis, the close individual touch, the sense of safety conveyed by the "atmosphere" I have spoken of, removes readily the obstacles to good psychiatric approach. These factors I believe, as exemplified in the case histories, shorten the period of illness and even give results that have not been nor cannot be expected in mass control.

And now I wish to come to the important phase of these observations, and by way of introduction to it, let me quote some sentences from a paper of Dr. Pollack's of our Mental Hygiene Department, "Family Care of Mental Patients." (*American Journal Psych.* Vol. 2, p. 331.)

The scientific spirit spurs us on towards the discovery of new and better methods of medical treatment and of more economical and more efficient methods of care.

Necessity also has spurs and is beginning to use them. The ever-present conflict between what we want to do and what we are able to do is growing in intensity and is threatening the mental health of the nation. Taxpayers groan under present burdens and are insistently demanding relief. The problem now before those vested with the care of mental patients is that of maintaining scientific standards while reducing per capita costs.

His paper further advanced the idea of family care for consideration. This proposal was later discussed at last year's Association meeting. The consensus of belief was rather pessimistic for its application in America. But it is evident that something must be done, for the problem is one of the most serious that confronts the social system of today.

From personal experience, and surely all whose experience is similar will support me, we can do more with treatment of mental disorders than we are doing. This is in no sense intended as a criticism of the personnel of our institutions or of their fine efforts. All will acknowl-

edge that we have come far, due to the work in our public institutions. However, this is a challenge to their spirit to again spur them to their task.

The past quarter of a century has been devoted to intensive research into the mechanics, and the understanding of the underlying qualities of mental disorders. It has somewhat supplanted the earlier phase of cataloging and grouping. And yet I fear we are spending, and are compelled to spend, so much effort upon the administration and the cataloging that treatment goes begging for want of attention and fresh energy.

As a constructive suggestion based upon an experience of close to a quarter of a century, I would propose treatment centers in each institution with special personnel, freed from institutional orthodoxy and emancipated from routine of administration and classification, who will give intensive treatment of a personal kind to selected groups, the sort that will incorporate all of the best in modern thought and also the kind that is inspired by personal challenge of the sick patient pleading for help from his only friend in this moment and need,—the doctor.

The admissions service should still function as a classification service and select the cases for the treatment centers, directing and segregating there, those cases offering the greatest need and the greatest promise for such treatment. It would be absurd to imply that all cases coming to a large institution can be benefitted by such a plan. But let's get at those who will be benefitted and get them back home or to convalescence by more intensive methods.

In such a brief offering as this I know that it is only possible to give a shadowy and inadequate idea, without any details of methods or plan. However, if I can sow the germ of the idea on fertile ground I am sure it will grow and develop to fruition.

305 PHYSICIANS BLDG.

Discussion

DR. H. S. GREGORY, *Binghamton State Hospital*—I quite agree with Dr. Boudreau that nursing homes rarely meet the needs of the average private psychiatric patient. They supply a bed and food and that is about all.

One gets the impression from reading

his brief case histories that a change in environment plus the ministrations of a sympathetic nursing staff, coupled with occupational therapy and, of course, therapeutic talks by the physician will often meet the needs of many mildly psychotic cases, who, if caught at the onset of the attack,

will respond promptly and readjust before chronicity claims them. Such an environment, in a private sanitarium, is available to relatively few patients because of economic considerations but an approximate approach to this set of conditions is worth striving for in the larger state institutions.

The proposal that treatment centers be arranged intramurally in large hospitals has been considered by many superintendents, though perhaps not in just the way outlined. Wards set aside for "habit training" purposes are not uncommon but are used largely for the rehabilitation of young schizophrenics whose routine of living has become sadly demoralized. In the Binghamton State Hospital such a ward limited to twenty cases, has functioned for the past eight years and the added expense as to personnel, etc., has been more than justified by the increased recovery rate.

Most hospitals attempt to make the wards of the reception service fulfill the idealistic conditions enumerated by Dr Boudreau and it is, of course, impossible of accomplish-

ment. All classes of patients must of necessity be admitted to such wards, and for a patient of refinement to be constantly associating with other patients of a much lower social level, often unable to speak English, can hardly be designated as "heart-balm" or as the "calming of a tortured soul." For such a person, with nerves on edge, to have to sit at a table in one of our state hospital dining rooms and see her compulsory table companions dipping into the stew with their fingers, is not to be considered good mental therapeutics. Yet we condone such situations and pass them over lightly with the comment that, "This is a public institution and taxes are already too high to permit of catering to any one class of society."

While I do not wish to be considered undemocratic, I must confess to being heartily in sympathy with Dr Boudreau's ideas and am going to continue to look forward to a more humane and sympathetic approach to a selected group of cases in our larger institutions.

HOW STATE MEDICINE WORKS IN AUSTRIA

Ten per cent of Austria's doctors "are totally unemployed and without means of subsistence," according to a special wireless dispatch from Reginald Sweetland to the *Chicago Daily News* Foreign Service, and 20 per cent are trying to live on fees of less than \$30 a month. This is under a regime of state medicine. It seems that of the 8,000 registered medical practitioners 7,000 are able to earn a subsistence wage in examining patients for the State social insurance scheme and Federal clinics. This number is to be reduced by about 4,500 under a new law which virtually closes the door of private medical practice.

Roughly 80 per cent of Austria's 6,000,000 population are beneficiaries in State

social insurance schemes and as such they get practically free medical attention, the State paying but a tip to the doctors qualified by the Government to deal with such State business.

Under the stipulations of the law of 1st April 1, which is now having disastrous effects upon the medical profession, 80 per cent of all Austrians under the social insurance scheme are limited in selecting their own private physicians, since the State pays the medical fees for such patients with the natural result that the Government, in usurping the clientele of private medical practitioners is reducing them to financial despair and destitution.

A suit to dissolve the Life Extension Institute, Inc., of 25 West Forty third Street and to annul its charter on the ground that it is practicing medicine without a license has been begun in the Supreme Court by Attorney General John J. Bennett, Jr., it was disclosed recently. The appointment of a receiver is sought in the suit.

The institute was incorporated in 1913 and has a present capitalization of \$2,000,000, according to the papers in the suit. It maintains a staff of physicians for conducting physical examinations and gives written reports on the results.

The Attorney General contends that this service constitutes practice of medicine. The institute maintains that the reports do not constitute practice of medicine, and that subscribers are always referred to their own physicians for treatment.

A British doctor who wished to pay a call at a cottage near Bracknell, Berks, made inquiries at the local post office. Finding the directions very involved he addressed a sixpenny telegram to the cottage and then accompanied the messenger.

CASE REPORT:

RUPTURE OF UTERUS DURING CURETTAGE WITH EXPULSION OF INTESTINES

RALPH F. WARD, M.D., F.A.C.S., *New York City*
and

HERMAN A. METZ, M.D., F.A.C.S., *New York City*

Case reports of this type in the American surgical literature are not very common. Because of the circumstances under which such accidents occur many, of necessity, must go unreported. In reporting this case, we wish to emphasize the comparative rarity of the lesion, the type of surgical procedure adopted and the remarkably rapid recovery. Following is the history of the patient in chronological order:

J. N., age 23, was brought to the Metropolitan Hospital by ambulance October 8, 1933, at 4:00 P.M. On the night of October 7 she had a fall which initiated vaginal bleeding that continued throughout that night. She had missed one menstrual period due about September 17. The morning of October 8 a midwife had attended her, and attempted a curettage of the uterus. During this procedure the uterus was ruptured and a loop of intestine brought down. Unaware at first of the true nature of the structure she was dealing with, the midwife cut across the loop of intestine. Realizing the seriousness of her error she summoned medical aid. Removal to hospital followed.

On admission the patient was pale, restless and complaining of severe abdominal pain. Temperature was 98.6, pulse 86, respiration 22, blood pressure 130 systolic and 0 diastolic. Vaginal speculum examination revealed what proved to be a severed loop of small intestine. Both limbs were probed and found to have lumina. Otherwise this tissue was stretched, ribbon-like and had no resemblance to intestine. Each of these structures from their point of emergence at the external os of the cervix measured approximately 6 inches in length and a half-inch in width. There was no visible mesenteric attachment. The ends were tied together with a ligature of catgut and vagina packed with iodoform gauze.

Under general anesthesia the abdomen was opened through a suprapubic midline incision. There was no bleeding or apparent soiling of the peritoneal cavity. In Trendelenburg position the abdominal contents were

packed off with hot pads and the uterus exposed to view. A loop of small intestine was seen entering a rent in the posterior superior segment of the uterus. The loop had been pulled down so thoroughly into the vagina that it acted as a cork, plugging the uterine rupture. This was a fortunate occurrence and accounts for the absence of soiling or active bleeding into the free abdominal cavity. During the preliminary exploration the intestinal loop was accidentally pulled out of the uterus. The tied ends were brought out on the abdominal wall and packed off with hot pads. Supravaginal hysterectomy was performed. In this manner a potentially infected organ was removed. End to end anastomosis of the severed loop was then performed after removal of crushed and nonviable gut.

An ileostomy tube was next inserted into the small intestine about one foot proximal to the anastomosis and brought out through a stab wound in the left rectus area. The ileostomy was to serve to divert the fecal stream and allow a better chance of healing of the anastomosed ends of intestine, as an outlet for gases and intestinal material and to avoid the development of ileus. The lower pelvic cavity was drained using two cigarette drains in the event the peritoneum had been soiled and infected during the operative procedure. Transfusion of whole blood was given immediately following closure of the abdomen.

Large quantities of fluid were given daily thereafter by intravenous and subcutaneous methods. For several days the postoperative course was stormy. A Levine tube was kept in the stomach on account of dilatation and frequent vomiting. The ileostomy tube functioned well from the beginning, loosened and fell out on the sixth day. Feces continued draining through this fistulous opening for another week. Bowel movements began on the seventh day. The patient was out of bed on the seventeenth postoperative day and home on the twenty-first. When seen five months after operation she had gained 10 pounds in weight, bowels were moving daily, and the abdominal wound was healed.

SPECIAL ARTICLE

HOW PSYCHIATRIC SERVICES ARE BEING UTILIZED BY SCHOOLS OF NEW YORK STATE

FREDERICK L. PATRY, M D, *Albany*

Psychiatrist, State Education Department

University of the State of New York

The following suggestions have been formulated, in the main, for school physicians with the confidence that they will be of assistance to them in rendering better total health service to school children. But teacher and student teacher, physical educator, nurse, attendance officer, guidance worker, visiting teacher and other school and college personnel may also benefit from critical evaluation and espousal of the concepts and recommendations presented.

Fundamental Concepts of Mental Health

The concept of health is in need of enlargement in order that the total health of the child will be kept in mind. It must be recognized that the individual reacts as a total unit and that things mental cannot be separated in reality from things physical since they are both part and parcel of the same organismic function. Anything which disturbs one component of the personality may have its repercussion in some other part. Psyche and soma must always be studied together.

It should be kept in mind that behavior is an integral aspect and expression of health, just as health is expressed in varying types of behavior. The latter should be regarded as a symptom of the individual striving to obtain satisfactions. When reasonable happiness and joy in adjusting to life are denied the child, he protests the situation by "nerves" or varying degrees of behavior and personality maladjustments. It is therefore incumbent upon the physician to know the facts of the child's mental and emotional life in order that he may understand the causes operating in the child's denial of satisfactions in twenty-four hour living. Just as important as the knowledge of facts of nutrition, appetite, weight, heart and lung functioning and other criteria

of physical efficiency, are the facts of the child's mental strivings and abilities. For example, we must know the child's mental age, gained by knowledge of the individual's life history in terms of developmental progress, social adjustments, school record and intelligence tests.

Frequently "nerves" or behavior difficulties are chiefly due to emotional strain caused by the child failing to gain satisfaction in school work because more is expected of him than he can meet with reasonable effort in the light of his intellectual capacity. Other frequent causes of maladjustments in school children are emotional conflicts causing strain because of unhappy home life, lack of home supervision and guidance, influence of unwholesome associates, educational factors contributing to failure in gaining social approval and recognition which contributes to reasonable prestige, denial of sense of belonging to the group, feelings of insecurity, and lack of freedom and opportunity to unfold his creative interests and abilities.

Cooperation, Understanding and Treatment

The school physician can learn much about the mental health of each pupil, if he will obligate himself to cooperate with the teachers in talking over successes and satisfactions of each pupil in adjusting to the curriculum and to his playmates. Since the teacher is in intimate personal contact with the child some five hours each day, she is in a strategic position to recognize early unwholesome behavior and personality reactions and to ascertain their causes. These in turn may be discussed to mutual advantage by teacher and physician.

Seek for Multiple Causes to Interpret Behavior. Behavior is in need of interpretation rather than judgment. If chil-

dren are to be happily adjusted to the school, to their fellow pupils, and to the home, we must find out the combination of causes or variables which contribute to unhappiness. Most maladjustments are essentially due to emotional dislocations, thwartings of desires, or arrests in emotional-social development.

Mental retardation in itself is not the cause of unhappiness or warped social integration, if we keep in mind the child's limitations and shape our program and expectations in keeping with his capacity to experience reasonable successes, a sense of achievement, and social approval or recognition.

Time Needed

The essential aspects of the mental life of a child can only be revealed by taking the time to win his confidence sufficiently for him to lay bare his wishes, longings, desires, strivings, successes and failures, disappointments and frustrations, ambitions and to what extent they are being realized in keeping with his capabilities and opportunities. The child's fears, anxieties and mood disturbances can only be appreciated by knowing the facts of the social environment which affect him positively or adversely in terms of life satisfactions.

Obviously the school physician himself has not time to gain all of the essential facts of each child's life history which are necessary to interpret inadequacies of adjustment and personality twists. Cooperation with the teacher, the parents, community agencies and other social contacts which cut in upon the child's twenty-four-hour living is essential.

The first line of defense in an organized mental health program is the classroom teacher, both from the standpoint of correction of maladjustments as well as from their early recognition and prevention. Her potential and actual contribution to the child's experience can be a most fruitful one in positive mental hygiene education. The aim is not only to maintain "normality" but also to develop each child's constructive potentialities to the optimum.

However, the full realization of these objectives will not be brought about until adequate cooperation is obtained from the parents and various individuals with

whom the child has intimate contact. Although the reading of well-chosen literature and courses in psychiatry and child guidance are helpful, the most fruitful source of knowledge comes by working with the child himself, applying what mental hygiene principles and practices can be gleaned from psychiatric literature as well as from clinical experience, co-operating with the classroom teacher, the physical education teacher, club associates and particularly the parents.

The starting point for the reconstruction program is recognition of the child's strengths, i. e., those things which bring him satisfaction. If we show each child to advantage on his own level of capacity to succeed, the negative aspects of behavior and personality deviations will recede into the background and disappear.

Specialist Often Needed

The latent potentialities of the school physician are manifold in capitalizing the mental health of each child. However, as is the case in all branches of general medicine, the services of the expert or specialist are required at times. It is important that the school physician recognize his limitations in the understanding and treatment of maladjusted pupils and that he get into the habit of referring such children to Child Guidance Clinics, Psychiatric Dispensaries in connection with hospitals or Health Centers, or to the psychiatrist in private practice.

Services of Department of Mental Hygiene

The New York State Department of Mental Hygiene offers its free services to school children in the form of its Child Guidance Clinics, Psychiatric and Psychological services available to schools throughout the State.

It is important that each school physician, as well as the school nurse, teacher, principal, and superintendent be aware of the location and clinic dates of the Child Guidance Clinic serving their school area. Each school should have its name placed upon the mailing list of the State Department of Mental Hygiene for a copy of "*Monthly Child Guidance Clinic Schedule*." The *Permanent Child Guidance Clinic Schedule* listing clinic location with fixed dates may also be obtained

upon application to the above Department. This schedule notes the place of meeting, its date of meeting, the psychiatrist in charge (who also checks up on the physical and neurological facts of each case) and the psychologist who does the required mental testing relative to intelligence, educational abilities and disabilities, aptitude, and other desirable test information. Each school should also have available the name of the "Field Agent" who is the local person making appointments for children to be examined at the Child Guidance Clinic. (The name and address of this worker may be had by writing to the State Department of Mental Hygiene.) In order that more children may not be taken to the clinic than can be adequately examined,* it is essential that the Field Agent be notified in advance of all persons desirous of clinic services. In other words, a definite appointment is necessary.

Special Class Intelligence Tests

The State Department of Mental Hygiene also provides psychologists for making intelligence tests of children who might be considered candidates for a special class because of varying degrees of mental retardation. The names of such children should be sent to the State Department of Mental Hygiene in order that a mutually convenient time may be arranged with the school for individual testing of a number of such children at one visit.

Exemption of Pupils from School

All children thought to be in need of exemption from school because of mental abnormality should have the advantage of an examination by a Child Guidance Clinic, where the psychological as well as the psychiatric and environmental facts of the case can be obtained and adequately evaluated by experts. The psychiatrist of the clinic will be glad to recommend exemptions and fill out the required forms of the State Department of Education. Frequently, children can be saved exemption from school by having the facts of

the case analyzed and interpreted by the personnel of the Child Guidance Clinic. They stand ready to cooperate with the school physician and other members of the school personnel, as well as the parents and family physician in serving the best interests of all children referred to them.

Children who are making unsatisfactory progress in school, who have personality difficulties or disciplinary problems, or for any reason seem to be misfit socially or educationally, are suitable candidates for examination at a Child Guidance Clinic. A child with speech defects can often be helped to unravel the various causes which may be operating. This may lead to the recommendation of educational, physical, social and psychological treatment which makes for the correction or improvement of various types of speech difficulty.

Whenever simple means fail to bring about readjustment, the services of more experienced and specialist type should be sought. Thus, early cases of maladjustment, which uncorrected may lead to delinquency and criminal behavior as well as to school failure, may be prevented.

Social workers and county agents may refer children to a Child Guidance Clinic for mental examination prior to placement or adoption. County and Children's Court Judges also utilize this type of service for advice and examination facts prior to commitment to an institution or other disposition. Children handicapped with physical defects which are associated with educational difficulties or social maladjustments should likewise have the advantage of this type of service.

Obtain "History" of Child

Before a child is sent to a Child Guidance Clinic, the school nurse, visiting teacher or field agent should obtain the requested facts of the history of the child. Copies of "Case History" form which contains suggestions for guidance in obtaining this information may be obtained upon application to the State Department of Mental Hygiene. This Department also furnishes the booklet "Child Guidance Clinics" describing their purpose and functioning; also eighteen leaflets and several booklets on mental hy-

* Only five or six new cases are usually examined by a Child Guidance Clinic in a single day. Follow-up service and advice is also given to pupils formerly seen at the Clinic.

giene subjects which should be of decided value to the school physician and other members of the school staff. These forms and booklets are furnished free of charge.

School physicians are urged to become thoroughly acquainted with and fully utilize the services of local psychiatric facilities, the Child Guidance Clinics, Psychiatric, Psychological, Social Worker and other special facilities and advice available through the New York State Department of Mental Hygiene.

In the event that there still is need of further psychiatric service by way of consultation, clinic or psychiatric education, the school physician should feel free to seek the assistance of the Psychiatrist of the State Education Department. Although his chief function is educational from the preventive psychiatric or mental hygiene angle, working for the most part with the classroom and student teacher, yet school physicians, school nurses, educational and vocational guidance workers, visiting teachers or psychiatric social workers, attendance officers, parental educators, psychologists, school administrators and other school personnel may also profit by the State Education Department Psychiatric Services in the event that the local psychiatric clinical, advisory or educational facilities available have been first exhausted or have proven inadequate for any reason.

Psychiatric Services to Teachers

Psychiatric services to teachers include discussion conferences and lectures on behavior, personality, emotional, social or educational problems presented by pupils, illustration of various methods of interpreting and handling pupil maladjustments, consultation service relative to individual pupil or teacher problems, panel discussions, and parent-teacher education meetings.

Literature

The school physician's attention is called to two free publications which may be had upon application to the State Department of Education: "*Examination of the So-called Bad or Nervous Child*" and "*Methodology in the Formulation of Mental Hygiene Case Studies*." A third booklet, "*Outlines of Personality Analysis and Reconstruction*," formerly published by the State Education Department, may now be obtained in a revised edition at cost price of ten cents from The National Child Welfare Association, 70 Fifth Avenue, New York City. These publications are of particular interest and service to the physician. The classroom teacher, student teacher, supervisor, school nurse and administrator also may utilize to good advantage the information and suggestions contained therein.

EDITORIALS

A Posse ad Esse

At the time when the report of the Wilbur Committee on the Study of the Costs of Medical Care was made public and was studied by the Booth Committee, set up by our Society, the first impression of all who studied the arguments enunciated by the Wilbur Committee was that the scheme would not work in this country. Medicine has battled the reactions which have ensued from the arguments advanced by the proponents of schemes which on one hand sought to bring about state medicine and on the other, to bring about a compulsory form of health insurance.

It is refreshing that there comes now from sources other than organized medicine thoughtful critiques which throw doubt on both the feasibility and the workability of not only these schemes but others proposed for the "betterment of mankind" in general and our people in this country in particular.

Thus, Robert Moses, in his article in the *Saturday Evening Post* of October twelfth, states

Let us assume that all the measures instituted and proposed by the national administration all the projects of the New Deal in their last implications, and all the corresponding and collateral changes advo-

cated locally in states and municipalities by its adherents are sound in principle and in the permanent interest of the average citizen, that they are the just due of the forgotten man, and even that they represent a perfect union of profound wisdom and inspired statesmanship * * * If all these assumptions are made, I still believe that the program sought to be imposed upon us is impractical because no government of ours can do it. It simply cannot be made to work. Our background and traditions are wholly against it. We have no experience and no standards to sustain it * * * A hundred or two hundred years from now the story may be different, but not within the lifetime of the youngest prospective voter now living.

In our arguments against the impracticability and non workability of the various schemes which organized medicine has opposed, the above quotation furnishes potent reasons which have always been the fundamental basis of our opposition to them. We have also always held that in this country, trained as we are as individualists, the best men in the profession would never join these schemes, and Mr Moses adds a trenchant observation to this and similar situations when he says "It is obvious that no matter how sound a program may be in theory, it is bound to fail if the administration brains

and personnel cannot be found, and the methods cannot be devised to make it work. * * * There is no well established tradition of competent, honest and enterprising public service in this country today, and there is no likelihood of establishing it on the gigantic scale now contemplated within any reasonable time."

These truisms, which must be apparent to any student of the American political scene, are not given enough serious and thoughtful consideration. In spite of them there comes from the adytum of the social reformers views which bring to mind the critical analysis of quackery in modern political and intellectual life recently made by Leonard Woolf, in which he points out that the effects of a false belief tenaciously held are often more powerful and devastating than those of true beliefs.

For the time being let us lay aside these arguments and look at the question from another standpoint. How will our wage-earners fare under the egis of the proposed change? We look in vain for that Labor Leader who is conscious of the narcotizing effect which these plans will have upon the laboring classes which tends to fix the worker permanently in a given income bracket, and prevent him from improving his position, and his station in life. The wage-earner gets less wages because he receives cheap medical service rather than so adequate a wage for his labor that he may, among other things, purchase the medical care he needs and wants.

It is a sad commentary on the course of events in our times and in this controversy to lose intellectual integrity in discussion. It is too evident that despite truths, false views are still promoted to the sanctity of absolute truths and labor is not yet awake to the dangers which threaten it. The organized medical profession is not battling for its own interests alone, because medicine in itself is the greatest social service in the community. It is concerned as much with the public welfare and what will happen to this, as it is in its own status.

Boon-Doggling

We are indebted to the Chairman of the Sub-Committee on Deafness and Hard of Hearing of the Public Health Committee of the Medical Society of the County of Monroe for bringing the following project, proposed by the WPA, to our attention.

This calls for a survey of deaf children of that county of pre-school age, sponsored by the Monroe County Regional Planning Board in connection with studies being made at the estimated cost of \$10,440, Monroe County to pay toward this project \$1,390. A study of this project reveals that it has no utility value. It presupposes subsequent training of the deaf child for which no provision is made in the project at all; and its value is emphatically questioned by prominent educators.

Since it is impossible to detect deaf children before the age of three years and since the public and special schools take them over at five years of age, the whole project is limited to those between the ages of three and five years. The prospectus which is drawn up about this survey states that the County of Monroe contains sixty of these children. Other evidence from the head of the Bureau for Handicapped Children in the New York State Education Department at Albany accounts for only fourteen of such, exclusive of those already in the Averill Avenue Nursery. Hence, it is intended to spend \$10,400 to survey these twelve or fourteen children.

The project is an unwarranted intrusion into a medical and educational problem by sponsors who are not certified as competent by either medical or educational authorities. It would seem that further comment would be unnecessary; and the Executive Committee of the State Society has gone on record as supporting the protest of Monroe County against this unwarranted project which adds to the taxpayer's burden and which is of no health value whatsoever. In times of great depression, such as we are

living through, it would hardly seem possible that funds could be wasted upon so futile a project

Malpractice Insurance

Considerable unrest is apparent in the ranks of our profession anent the ensuing change in insurance carrier from the Aetna to the Yorkshire Indemnity Co.

Suffice it here to re state that the financial responsibility of the Yorkshire Indemnity Company has been subjected to a searching study and has been found adequate. The officials of our Society, having this matter in hand, have found ample security is afforded our members who will become policy holders with the new carrier.

To the confusion produced in the minds of the members by the change there has been added the activities of local insurance agents who are naturally interested parties seeking to retain business and who, in some instances, seem to have activated objections and objectors to the change in carrier. The Society's insurance representative, Mr. Wamvig, is available to county organizations for information and other related service.

Before hastily conceived objections are raised, would it not be well to be properly informed from authoritative sources?

Every Vote Counts

The elections to be held on November fifth will go far to determine the complexion of the next State Legislature. Many people forfeit their votes in these off years because of the general absence of sensational campaigning and the fact that no high executive office is involved. To any one who stands to be influenced by legislative action, however, the caliber and views of the candidates up for election next week are of the utmost importance. Physicians fall within this class.

There seems little doubt that compulsory health insurance will come before the State Legislature in January. If it is incorporated in the federal program for

economic security, the latter will be submitted for ratification. If not, the forces that have sponsored similar legislation locally in the past will undoubtedly act again on their own initiative.

This is not the only measure of professional import which crops up each year. Every session witnesses new attempts to expand the list of presumptive occupational diseases. Osteopaths demand privileges beyond the scope of their training, lay physiotherapy technicians attempt to shake off necessary restrictions on their freedom of action, and various public departments seek to encroach on private medical practice. On the other side of the picture, physicians are deeply interested in legislation to safeguard their professional independence, secure the economic status of medicine and advance the public health.

Most of the men who are up for election have been in the public eye before and, by past actions, have demonstrated whether the interests of scientific medicine may safely be entrusted to their hands. Those seeking office for the first time cannot put themselves on record too soon on questions vitally affecting medical practice and the public health. Every doctor should vote at the coming election—and before voting should ascertain the views of the candidates for whom he proposes to cast his ballot on all important professional issues.

Possible Opportunities

A recent issue of the *NEW YORK STATE JOURNAL OF MEDICINE* reprinted some of the results of a "location survey" conducted by *Medical Economics*. They reveal that seven towns in New York State with more than a thousand inhabitants each have no physicians. These are Colonie, with a population of 1176, Great Neck Estates, with 1738, Hillburn, with 1303, North Pelham, with 4890, South Nyack, with 2212, Stewart Manor, with 1291, and West Carthage, with 1722.

In Irondequoit Town, the proportion is 6008 persons to every physician, in

New York Mills 4006 and in Sloan 3482. Three communities.—East Rockaway, Elmira Heights and South Glens Falls—have one doctor to every twenty-one to twenty-seven hundred of population. In Port Dickinson and Solvey the ratio is over nineteen hundred to one and in Yorkville over 1700. Three more towns—Green Island, Rensselaer and Scotia—follow up closely with over 1400 of population to each practitioner. Depew, Dunkirk, East Rochester, Massena and Watervliet are next with 1300 and more; while Lackawanna, Little Falls and North Tonawanda top twelve hundred, eleven hundred and a thousand respectively.

If these figures are correct, they are an impressive argument for better distribution of physicians in this state. The average ratio of practitioners to population in the United States is one to 866. The great disproportion in the twenty-eight towns cited by *Medical Economics* suggests that unless some special condition prevails these localities would benefit by an increase in the percentage of physicians and there is an opportunity for a limited number of medical men to build up a practice in communities that need more doctors.

In a number of small towns throughout the country that formerly had no physicians—notably Ogema, Wisconsin—practitioners have been able to earn a good livelihood by securing retainers from a sufficient number of families to guarantee at least minimum expenses. Statistics rarely tell the whole story and the figures elicited by *Medical Economics'* "location survey" may mask peculiar circumstances—but the towns mentioned appear to hold out at least a promise to any one interested enough to investigate.

Whooping Cough

Since the inception in 1906 of attempts to produce an active immunity against whooping cough, the literature has abounded with reports from pediatricians and epidemiologists concerning the feasibility of vaccination for the prevention of

pertussis. From the reading of these published reports, one is impressed by the marked discrepancies which exist among the various observers. These are due, perhaps, to the fact that until recently no standard of comparison has existed. Different investigators used the vaccine at different times in relation to the onset of the disease. Another factor which precludes a comparison of results is the varying dosage employed in experimental observations. Then again, the vaccine was employed by some of the investigators in age groups which differed from those used by others engaged in the study of the same problem. By far the most important factor, however, has been the use of vaccines made from cultures of *B. pertussis* without regard to the age of the culture. The significance of utilizing a vaccine made from an old culture or from one just recently isolated has been stressed only in the recent literature.¹

The investigation of the problem has been handicapped further by the doubt which has been cast upon the specificity of the *B. pertussis* as the cause of whooping cough. McCordock and Muckenfuss² suggest the possibility of a filterable virus as the direct etiological factor, but the fact that the *B. pertussis* is found in all cases of whooping cough while not recoverable in the absence of the disease would tend to discredit this view.¹ Furthermore, the ability to reproduce whooping cough in animals³ and in children⁴ by using *B. pertussis* affords presumptive evidence of the causative role played by this organism.

The lull in the study of this problem

has been replaced lately by a renewed interest, due largely to the more recently acquired knowledge of the antigenicity of the cultures utilized and to the more favorable results which have been reported by Madsen⁵ and Sauer⁶. At the present time, no definite evaluation of the efficacy of vaccination against whooping cough is possible. A reinvestigation of the entire subject is needed and careful controls and prolonged study will be required before any appraisal can be made of its practical applicability.

Operability of Gastric Carcinoma

To most laymen and to many physicians, carcinoma of the stomach presents a hopeless outlook from both a therapeutic and prognostic viewpoint. Certainly, the statistical compilation of the American Society for the Control of Cancer, which revealed that gastric and duodenal carcinoma was responsible for twenty two per cent of the 115,256 reported deaths from cancer for the year 1930¹ would tend, at first glance, to support this pessimistic attitude. On closer analysis of these figures, however, they indicate merely the high incidence of cancer located in the stomach and consequently are not intended to be used as a prop for despair.

The fatality of gastric carcinoma to no small degree is dependent upon the difficulties encountered in recognizing the lesion before it becomes inoperable. That other factors play an important part in prognosis is admitted by all concerned in the study of this subject. In the main, however, the high percentage of deaths resulting from carcinoma of the stomach has been due to the low index of opera-

bility hitherto existent. Reports show a wide variation in the percentage of operability, ranging from 30%² to 70%³. All observers, in the discussion of this phase of gastric malignancy, confine their statistics to those cases which lend themselves to curative as contrasted with palliative surgery. Thus Hunt¹ speaking in terms of gastric resection, states that, of the cases which have come under his observation, 36.2% were operable.

The low figures reported, therefore, are the result of conditions beyond the control of surgery. Despite the high degree of accuracy attained in the detection of carcinoma of the stomach, early diagnosis at times is extremely difficult. In many instances the lesion, when recognized, has advanced beyond the stage of operability. Many cases of gastric carcinoma present clinical manifestations of inoperability when seen for the first time. Lesions of the cardia or of the upper lesser curvature are considered as inoperable by many observers. These are some of the factors which decrease the index of operability for cancer of the stomach.

The outlook for the future is nevertheless a favorable one. Not only does there appear to be a definite tendency toward the achievement of a higher operability but the curability of the disease also shows an upward trend. Gatewood⁴ reports that, of his operable cases, 39.5% are alive after five years. The intensive campaign of instruction which has made the public more and more alert to the importance of trivial gastric symptoms, has brought many more sufferers to the operating table in the earliest stages of carcinoma of the stomach. The increase in the percentage of operability goes hand in hand with the prolongation and saving of life and the continuance, even

the intensification, of propaganda directed toward making the public and the profession "cancer conscious," will go far toward augmenting the advance thus far attained.

CURRENT COMMENT

MR. ROBERT MOSES, in the *Saturday Evening Post* of October twelfth, says, "If a choice must be made between an economic and a political sycophant, the political sycophant is probably the less dangerous of the two. He is more likely to give the public a break between elections, and less likely to corrupt the text of official reports."

FROM THE ADDRESS of Mrs. Rogers N. Herbert, President of the Womans' Auxiliary of the A.M.A., we cull "What is the major objective of the Womans' Auxiliary? * * * To interpret intelligently to the laity the great underlying purposes of the A.M.A."

IN THE *Journal of the American Medical Association* of October 19th, commenting on the trend in development in public health service, the *Journal* says that "For years both physicians and public health officials have urged greater appropriations for public health. They now find themselves in the position of a starving man suddenly seated at a ten-course banquet. There is too much food for possible digestion and the end result is certain to be a 'stomach ache.' It is no secret that health officers in high positions are in a dilemma as to the disposition of the money now to be showered on them. Neither the personnel nor the projects have been developed for suitable spending of these appropriations. The announcement has been made that a survey of 750,000 families is to be conducted by the United States Public Health Service to determine the status of their health and the care given to them in disease. Yet the opinion has already been ventured by the assistant secretary of the treasury in charge of the United States Public Health Service that the answer to this survey is apparent." If the answer is already available, why make a survey? We have commented editorially last month on the fact that this survey probably was eventually to furnish propaganda based on a theory that a large proportion of our population is not receiving adequate medical care. We very much fear that our surmises are going to prove to be correct.

EDITORIALLY, the *Journal of the American Medical Association* of October 19th, in its discussion of the debate on state medicine,

brings the illuminating information that the Ninth Annual Debate Handbook, edited by Bower Aly, indicates that the American College of Surgeons favors compulsory sickness insurance, notwithstanding the fact that the governors of the college have specifically denied this allegation. In justice to the many members of the college, this denial should be made more emphatic so that nobody misunderstands the position of the college.

IN THE SAME EDITORIAL it is stated that "President Roosevelt has said, at least so Mr. Moley affirms, that there will be no attempt at a program of compulsory health insurance until public sentiment has crystallized in that direction." There does not seem to be much evidence of crystallization except from certain interested quarters.

Medical Week of October 19th, editorially discussing support for graduate education, quotes Dr. Willard C. Rappleye, Dean of the College of Physicians and Surgeons of Columbia University, "the annual budget of the medical schools of the United States totals more than eleven million dollars, about a third of which is provided by student fees. Less than three per cent of the entire amount is allotted to graduate instruction. If the latter 'is to be placed on a proper educational level, more financial support for university programs in this field will have to be secured.' * * * Philanthropists interested in elevating the standards of medical care could accomplish a great deal by diverting to graduate medical education some of the funds now trickling away in sentimental and theoretical movements. * * * Quoting Dr. Rappleye again, 'The great need of the country is for better, not more physicians and for opportunities by which those in practice and those who are qualified to specialize may be able to prepare themselves adequately, for their responsibility to the public.'"

PRESIDENT GEORGE BARTON CUTTEN of Colgate University recently issued a provocative thought when he said that "I have attended religious gatherings—some of a national character. I have even been to prayer meeting—an outworn and mid-Victorian custom—but I have yet to hear from pulpit or pew a person who prayed, 'Lord give us more hard times!' Yet, if the God of nature and the God of the Church are the same, He has been trying to teach us since cons before the dawn of history that hard times are the hotbed of progress, and easy times are the harbingers of degeneration and downfall." In brief, he holds that competition is necessary for progress because a man really must be kicked upstairs.

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked by rule. All communications must carry the writer's full name and address which will be omitted on publication if desired. Anonymous letters will be disregarded.]

To the Editor

There are 62 counties in New York State. There are 60 County Medical Societies in New York State, but Putnam County, having separated from Dutchess County, there will soon be 61 County Medical Societies.

As Organizing President of the Woman's Auxiliary to the Medical Society of the State of New York, I sent out on August first, 57 letters to the presidents of the County Medical Societies in which there are no Woman's Auxiliaries. In these letters, I asked for the permission and cooperation of the Medical Societies to organize a Woman's Auxiliary to each County Medical Society.

At present date, October 14, I have had responses from 15 counties. Many have been very enthusiastic, a few have been only slightly interested but none have been entirely opposed. I am still hopeful that I shall hear from the remaining counties at an early date.

There is no better way for me to bring to your attention the aims and purposes of a Woman's Auxiliary, than to quote from the splendid inaugural address of Mrs. Rogers N. Herbert, President of the Woman's Auxiliary to the American Medical Association.

Mrs. Herbert stressed the importance of the latent potentialities of the Woman's Auxiliary to the American Medical Association, and said that the major objective of the Woman's Auxiliary is to interpret intelligently to the laity the great underlying purpose of the American Medical Association and that the problem of *how* is to be solved by the Auxiliary, as guided by the Advisory Council.

She spoke of yearly changed conditions and new attitudes toward the medical profession. To quote:

It is our inalienable right as the biological helpmates of that great body of men, who are giving their life, their time, their all to the noblest of all professions, medical science, that we should uphold their hands and assist them in perfecting their chief purpose—that of promoting a great Health Program. * * * The State and County Auxiliaries are the only mediums by which the National can function effectively.

To quote further:

Today, throughout the world we are witnessing the entrance of woman into every post of service for her country. * * * the largest

body of women, General Federation of Women's Clubs encircling the world with its splendid educational opportunities has included in its broad curriculum the study of Health * * * the most vital subject of the entire Auxiliary program, since it relates and integrates every phase of life—living. Health education is fighting to hold the gains it has made. * * *

The President called upon Auxiliary workers to make a greater effort to cooperate with other organizations that they may sound the alarm in calling attention to the crisis in Health Education. She emphasized that in matters of legislation, touching the medical profession, not only physicians' wives but every woman should be informed, that it is of vital importance that the workers of each state should know the legislation of that particular state as touching this important subject.

On Public Welfare, she said:

For the past few years, Public Welfare has played such an important part in community interests, that no woman can afford to lag behind.

She stated further that through the daily press, periodicals and radio, the mind of the Public was being informed concerning Medical Science and that the Auxiliary members should keep so well informed that they will readily recognize whether the lay mind is being *informed* or *misinformed*.

Finally she asserted:

It is incumbent upon the Auxiliary woman * * * to bring about a spirit of cooperation between the Medical Profession, Social Agencies, Public Health Department, and the laity.

Then again she stressed that for the solution of any problem the Advisory Council, both State and County, should be consulted not only as a matter of Auxiliary ethics, but of wisdom and safety.

Mrs. Herbert concluded her address with:

Facing the dawn of a new Auxiliary year, let us remember that *Behind us is Infinite Power. Before us is endless possibility, Around us is boundless effort.*

It was my privilege to hear Mrs. Herbert address the Convention last June in Atlantic City. I assure you the hundreds of Auxiliary members were inspired, and the State presidents accepted the challenge.

MRS. JOHN L. BAUER

Organizing President of the Woman's Auxiliary to the Medical Society of the State of New York

Society Activities

Executive Committee Proceedings.

Action was taken by the Executive Committee at its regular meeting on October 10, 1935, on three matters that merit the attention of the membership.

In accordance with a request of Dr. Olin West, Secretary of the American Medical Association, it was decided to advise all members to read in the October 5, 1935 issue of the *Journal of The American Medical Association* an article "The New Health Survey" on page 1127 and the editorial on page 1121 which also refers to the subject.

* * *

In connection with queries on the change in arrangements for group malpractice insurance the following resolutions were adopted:

That the members of the Society be informed of the details of their malpractice insurance by publication in the State Journal of a chronological sketch of events which led up to the change of carrier and the additional advantages enjoyed by the profession under the new policy.

That a statement of financial responsibility of the Yorkshire be published together with the rating from Best's manual.

That Mr. Wanvig make himself available to any component County Society desiring a discussion of malpractice insurance upon request.

* * *

From the Medical Society of the County of Monroe was received word of a protest against a W. P. A. project in that county, coupled with a request for approval by the State Society. The following letter explains the situation:

September 27, 1935

Dr. Robert G. Hoffman
District Director W. P. A.
1460 South Avenue,
Rochester, New York.

Dear Mr. Hoffman:

As Chairman of the Sub-Committee on Deafness and Hard of Hearing of the Public Health Committee of the Medical Society of the County of Monroe, I wish to file formal protest, in the name of the Society, against the proposed W. P. A. project, calling for a "Survey of deaf children of the County of pre-school age, a project sponsored by the Monroe County Regional Planning Board in Connection with studies being made at an estimated cost of \$10,440 with the County to pay \$1,390."

We protest this project for the following reasons:

First: The survey in and of itself has no utility value. It presupposes subsequent training of the deaf child for which no provision is made within this particular project and the value of which is emphatically questioned by prominent educators in this field.

Second: An unwarranted expenditure is proposed for a project of questionable value. Since it is almost impossible to detect deaf children before three years of age, and since the public or special schools take them over at five years of age, the whole operative field is limited within the ages of three to five. The prospectus for this project states that there are within the County of Monroe some sixty of these children. According to Mr. Joseph M. Enders, Head of the Bureau for Handicapped Children in the New York State Education Department at Albany, there are probably within the County twelve to fourteen of such children, exclusive of the seven now in the Averill Avenue Nursery for pre-school deaf children. The sum of \$10,400 is to be spent to detect these twelve to fourteen children. (The prospectus says sixty.)

Third: In another two or three years the findings of the proposed survey will be obsolete and useless. These children will have passed on into the public school age, and the newborn deaf children will again have to be detected at the rate of \$10,400 for twelve to fourteen children. (The prospectus says sixty.)

Unless some scheme for the continuous detection of such children as they become three years of age could be worked out, there is no permanent value in such a project nor does it have any justification.

Fourth: It is common knowledge among otologists (ear specialists) that such an investigation is neither desired nor will be welcomed by those most vitally interested, namely, the parents of the congenitally deaf. Parents often shield and protect these children from inquiring and investigating individuals as long as possible.

Fifth: Such a survey is bound to be inaccurate and inadequate because:

(a) Otological (ear) examinations are absolutely necessary to the project. The prospectus states, however, that this is not a medical project. (b) The census-takers will have difficulty in getting the parents to admit that a child three years old is deaf. They insist that he has not yet begun to talk, and in some cases they are right. (c) So far as we know, there is no authority that compels parents to give the census-taker such information anyway.

Sixth This project is an unwarranted intrusion into a medical and educational problem by sponsors who are not certified either medically or educationally

Seventh If this project had any justification, which the Medical Society of the County of Monroe feels that it has not it should be definitely a community medical and educational problem and should be handled only by medical and educational authorities. Both these groups have been ignored

Further, the feeling among many physicians and educators is that since the family doctor is both physician and confessor, he will be the first person to detect these deaf children and through his personal contacts and the cooperation of the County Medical Society their best interests will be served, and no elaborate set up or useless expenditures of money would be involved

We are submitting this protest with no thought other than to clarify the subject and prevent unnecessary waste of funds and effort. It is the attitude we would assume in opposing

any other public project upon which our special training qualified us to speak

Yours very truly,
(Signed) C. Stewart Nash, M.D.
Chairman Sub Committee on
Deafness and Hard of Hearing

Willard H. Veeder, M.D.
President Medical Society
of the County of Monroe

E. G. Whipple, M.D.
Chairman Public Health Committee

On formal motion the Executive Committee resolved

That the action of the Medical Society of the County of Monroe, protesting against the proposed WPA project calling for a survey of deaf children of pre school age be heartily endorsed and that due publicity be given to the action in the State Journal

D. S. DOUGHERTY, M.D.,
Secretary

County Societies

Erie County

Dr. E. J. MEYER, prominent Buffalo physician and president of the Buffalo City Hospital Board of Managers died suddenly on September 13 of a heart attack. He was 66.

Dr. Meyer was stricken as he sat with a group of friends aboard his yacht, in the Buffalo Yacht Club basin. He died within a half hour despite the efforts of Dr. P. J. Walsh, his personal physician, who was aboard the yacht, to revive him.

He was called the father of the City Hospital, leading the drive in 1927 for a bond issue of \$2,169,216 for additions to the institutions, a project defeated, however by a referendum after a bitter controversy among physicians and citizens.

In 1931 the medical and surgical buildings of the hospital were completed and dedicated to Dr. Meyer in recognition of his services.

At a special meeting of the Board of Managers, Buffalo City Hospital, held September 16, 1935 for the purpose of taking suitable action regarding the death of Edward J. Meyer, M.D., President the following was enacted:

Whereas Edward J. Meyer, M.D., on May 27, 1912, was appointed a member of the Board of Managers Buffalo City Hospital by the Honorable Louis P. Fuhrmann Mayor and immediately thereafter was elected President,

which office he held continuously until his passing, and

Whereas, Under his guidance the Board of Managers acquired a site for and accomplished the construction and equipment of a public general hospital at a cost of approximately four million dollars for the reception and treatment of all diseases and

Whereas, Due to his leadership the Buffalo City Hospital from the start assumed an outstanding position as one of the few general hospitals, public or private, in the United States, and

Whereas Acting upon the recommendation of our distinguished President, the Buffalo City Hospital has furnished a complete medical service to all residents in the community, and

Whereas, Edward J. Meyer, M.D., fostered a close union between the University of Buffalo and the Buffalo City Hospital for the purpose of promoting the education of physicians, dentists, nurses and dietitians, thereby assuring the highest type of service to patients and

Whereas, During his lifetime he attained an outstanding position as a surgeon and throughout his entire career worked for the advancement of the profession which he adorned and loved, therefore be it

Resolved That the passing of Edward J. Meyer, M.D., is a grievous loss to his family and friends and the community in which he was born and reared, that his record as a voluntary public servant stands, in local annals unequalled for length of service and unexcelled for probity and wisdom and be it further

Resolved That the inscription on the brass

tablet placed in the Buffalo City Hospital during his lifetime, June 1932, as a permanent memorial be reaffirmed as follows:

The medical and surgical buildings comprising this unit are dedicated to

EDWARD J. MEYER, M.D.

Born August 15, 1869

President, Board of Managers, Buffalo City Hospital, since May 27, 1912, Appointed by Honorable Louis P. Fuhmann, Mayor.

"Record in the Medical School, University of Buffalo

Graduated in Medicine.....	1891
Surgeon on Dispensary Staff.....	1893
Instructor in Surgery.....	1895
Adjunct Professor of Clinical Surgery.....	1898
Assistant Professor of Surgery.....	1916
Emeritus Clinical Professor of Surgery.....	1919

"Dr. Meyer has labored long and faithfully in the interests of the Buffalo City Hospital. Throughout the years, he has held, steadfastly, that the functions of a hospital are, first:—care of the patients—second:—training physicians, dentists, nurses and dietitians—third: research. His motto has been: "Salus populi suprema lex esto."—Cicero, (Let the health of the people be the supreme law.)"

ERECTED JUNE 1932

And be it further

Resolved, That these resolutions be inscribed on the minutes of the Board of Managers, Buffalo City Hospital, and a formal copy of the same presented to his family.

Oneida County

FOR THE SIXTH CONSECUTIVE YEAR the golfing team of the Syracuse Academy of Medicine gained possession of a loving cup from the Utica Academy of Medicine players.

The visitors won their annual match at the Yahnundasis Golf Club in Utica, on September 19th, by 930 to 963, those figures representing the aggregate medal scores of players.

At a brief business meeting prior to the annual dinner, Drs. W. Roy Van Allen, Utica, and John H. Powers, Mary Imogene Bassett Hospital, Cooperstown, were accepted as members of the Utica Academy. Six new members were proposed and will be voted on at the next meeting.

Dr. F. M. Miller, Sr., president of the Utica Academy, presided at the dinner and business session and introduced Dr. Adelbert Abbott, who gave a brief address. Dr. H. Walden Retan of Syracuse, a member of the entertainment committee, was master of ceremonies for the program, which included songs and two skits by Dr. Orren D. Chapman.

Results of the golf tournament:

Syracuse—Pelow, 81; Gilmore, 84; Cain, 93; Andrews, 92; Werfelman, 92; Dye, 95; Rulison, 97; Laurie, 97; Walsh, 98; Allen, 101—930.

Utica—Moffatt, 88; Grant, 93; Gage, 92; Sloan, 91; B. Golley, 92; Remmer, 92; McMillen, 103; L. Golley, 104; Pender, 104; Groff, 104—963.

Queens County

MEMBERS OF THE WOMEN'S AUXILIARY of the Queens County Medical Society attended a dinner on September 24, at the Forest Hills Inn, under the auspices of the Queensboro Tuberculosis and Health Association and the Queens County Medical Society.

After the dinner the auxiliary opened its season with a short meeting in the Medical Society Building, Forest Hills. After its own meeting members attended a joint meeting of the Tuberculosis and Medical Societies in the same building.

The annual dinner-dance of the auxiliary will be held November 9 at a Manhattan hotel.

First District Branch

The feature of the meeting of the First District Branch of the State Society on October 8th was a strong attack on compulsory sickness insurance made by President Frederic E. Sondern. "The figures in the United States and Canada, where there is no State medicine, show morbidity and mortality are the lowest in the world," he said, "England and Germany, where they long have had government supervision, are ten years behind us."

Other speakers were Drs. John J. Moorehead, Hugh Auchincloss, George Miller MacKee, Byron Stookey, Daniel Dougherty and Terry M. Townsend, president of the District branch which includes the counties of the Bronx, New York, Westchester, Rockland, Dutchess, Putnam, Orange, and Richmond. About 100 physicians were present. The sessions were held at the Hotel Pennsylvania in New York City.

Third District Branch

The Third District Branch of the State Society met at the Hendrick Hudson hotel in Troy on September 24, with a large attendance. Addresses were made by President Sondern and Drs. L. C. Kress of Buffalo, C. J. Handron of Troy, E. H. Campbell, Jr. of Albany and Warren Wooden, of Rochester. The paper prepared on "The Legal Aspects of Malpractice," by Atty. Thomas H. Guy of Troy was read by his law partner, Atty. John Broderick, Mr. Guy being out of town. Many of the physicians gathered at the meeting spent the forenoon visiting the Troy, Samaritan and Leonard Hospitals; others visited the Maternity Hospital, Pawling Sanatorium and Marshall Sanatorium. The Third District Branch includes the counties of Albany, Rensselaer, Schoharie, Greene, Columbia, Ulster, and Sullivan.

Fourth District Branch

The modern treatment of pneumonia was the main topic of discussion at the annual meeting of the Fourth District Branch of the State Society at Saratoga Springs on September 27 and 28. This district includes the eleven counties of St. Lawrence, Franklin, Clinton, Essex, Hamilton, Fulton, Montgomery, Schenectady, Saratoga, Warren, and Washington. Dr. Russell L. Cecil of New York City explained in an interesting address the details of the attack on pneumonia which medical societies are preparing to make throughout the state during the coming months. Other speakers were Drs. A. L. Lockwood of Toronto, L. W. Gorham of Albany, W. S. McClellan of Saratoga Springs, Howard Lihenthal of New York City, and T. F. Farmer of Syracuse. President Sondern was the chief speaker at the dinner meeting on Friday evening.

Fifth District Branch

Silicosis and its relation to industry and tuberculosis was the subject of an informing discussion at the annual meeting of the Fifth District Branch of the State Society at the Black River Valley Club at Watertown on October 1st. The district includes Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga, and Oswego counties. Papers on silicosis were presented by Drs. C. C. Trembley of Saranac Lake, and D. M. Brumfiel and Mr. O. G. Browne, of the claims department of the New York Central Lines. President Sondern described the plans for a statewide drive on pneumonia. Other papers were presented by Drs. Murray M. Gardner of Watertown and Dan Mellen of Rome. Dr. Gardner was elected district president to succeed Dr. L. F. Hollis of Lacona.

Sixth District Branch

Dr. George W. Crile of Cleveland, Ohio, was one of the outstanding speakers to address the physicians gathered at Elmira, September 18, at the annual meeting of the Sixth District Branch of the State Society. He came by special invitation to describe the use of surgery in certain types of heart disease. Another invited speaker was Dr. Austin A. Hayden of Chicago, who gave an illustrated lecture on the activities of the American Medical Association, of which he is a trustee. The district embraces the nine counties of Broome, Chenango, Chemung, Cortland, Delaware, Otsego, Schuyler, Tompkins, and Tioga. Other speakers were President Frederic E.

Sondern, Dr. Ethan F. Butler, Elmira, Dr. Herbert M. Bergamini, New York City, Dr. Leon F. Sutton, Syracuse, and Dr. John F. McCarthy, New York City.

Dr. Leo P. Larkin of Ithaca was elected district president, Dr. Reeve B. Howland of Elmira, was elected first vice president, Dr. Hubert B. Marvin, Binghamton, secretary, and Dr. William A. Moulton, Candor, treasurer.

Seventh District Branch

An important paper on infantile paralysis was presented by Dr. J. A. Kolmer, of Philadelphia at the annual meeting of the Seventh District Branch of the State Society at Canandaigua on September 26, discussing susceptibility, immunity, and vaccination. Other speakers included Dr. Frederic E. Sondern of New York City, state society president, Drs. Floyd S. Winslow, James M. Flynn, E. T. Wentworth, and Warren Wooden of Rochester, Joseph S. Lawrence of Albany, Raymond F. Johnson of Auburn, Nelson G. Russell of Buffalo, Wardner D. Ayer of Syracuse, Thomas W. Maloney of Geneva, Howard M. Clute of Boston. The district includes the eight counties of Monroe, Wayne, Cayuga, Seneca, Yates, Ontario, Livingston, and Steuben. The meeting was held at the Veterans' Hospital where Dr. Hans Hansen, manager, offered visiting physicians an opportunity to examine the facilities established there for the treatment of neuropsychiatric conditions.

Eighth District Branch

A discussion of medical relief under the TERA featured the morning session of the Eighth District Branch of the State Society at Warsaw on October 3 following an address on the subject by Dr. H. J. Davis, Director of Medical Care, TERA, and Consultant in Medical Care, PWA, New York City. The statewide drive on pneumonia was described by President Sondern at the afternoon session, Dr. H. K. Thompson of the Tufts Medical School spoke on "The Management of Arthritis," and Dr. G. de Takats of Northwestern University spoke on "Peripheral Vascular Disease." This district embraces the eight counties of Allegany, Cattaraugus, Chautauqua, Erie, Genesee, Niagara, Orleans, and Wyoming. Dr. H. W. Ingham of Jamestown, was elected district president, Dr. Herbert A. Smith, Buffalo, first vice president, Dr. L. L. Klostermeyer, Warsaw, second vice president; Dr. Henry M. Spofford, Batavia, re-elected secretary, Dr. Fitch H. Van Orsdale, Belmont, re-elected treasurer.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Ownership of X-Rays

Previously in these columns we have commented upon the legal aspects of the question of the ownership of x-rays. Very recently a case* came before the highest court of one of the Mid-Western states which squarely presented the question as to whether x-rays belong to the physician. It is necessary to detail the facts of the case to some extent to properly appreciate the ruling.

An employee of a highway construction company was injured in the course of his employment and the company engaged Dr. M. to give the workman the necessary medical or surgical care. The doctor attended the patient over a period from September to the following January. It appeared that the workman had been using a crowbar which in some manner slipped, and caused him to wrench his body so as to cause lower back injuries involving the sacroiliac joint. Incidental to the treatment various x-rays were taken by the doctor. Afterwards the employer of the patient had demanded the x-ray negatives from the doctor for use by other physicians, and he had refused to hand them over, although he expressed willingness to permit their inspection if not removed from his offices.

When the doctor's bill was presented to the company, it declined to pay and he brought an action to enforce payment. The defendant company admitted the employment but set up as defenses the claim that the employee's condition was not frequently enough reported to the defendant by the doctor, and the fact that the plaintiff had refused to deliver the x-ray negatives to the company when demanded.

Upon the trial a verdict was rendered in favor of the doctor by the Court sitting without a jury. An appeal was taken by the defendant company to further test out the validity of its defenses.

The first defense relative to failure to report was disposed of by the Appellate Court, with the finding that the plaintiff had not failed to report the workman's condition when requested, and that there had been no understanding specifically made to make any particular number of such reports.

The Court, in rejecting the second defense, specifically held that the plaintiff had been entitled to retain the x-ray negatives, and in its opinion, said in part:

Further, plaintiff was fully justified in refusing to surrender possession of the x-ray negatives. In the absence of agreement to the contrary, such negatives are the property of the physician or surgeon who has made them incident to treating a patient. It is a matter of common knowledge that x-ray negatives are practically meaningless to the ordinary layman. But their retention by the physician or surgeon constitutes an important part of his clinical record in the particular case, and in the aggregate these negatives may embody and preserve much of value incident to a physician's or surgeon's experience. They are as much a part of the history of the case as any other case record made by a physician or surgeon. In a sense they differ little if at all from microscopic slides of tissue made in the course of diagnosis or treating a patient, but it would hardly be claimed that such slides were the property of the patient. Also, in the event of a malpractice suit against a physician or surgeon, the x-ray negatives which he has caused to be taken and preserved incident to treating the patient might often constitute the unimpeachable evidence which would fully justify the treatment of which the patient was complaining. In the absence of an agreement to the contrary, there is every good reason for holding that x-rays are the property of the physician or surgeon rather than of the patient or party who employed such physician or surgeon, notwithstanding the cost of taking the x-rays was charged to the patient or to the one who engaged the physician or surgeon as a part of the professional services rendered. Careful research indicates that the question here presented is one of first impression. While not fully to the point, it has been indicated by court decisions that the negative of an ordinary photograph, in the absence of an agreement otherwise, belongs to the operating photographer, though his use thereof may be restricted.

The court's ruling in the case is in accord with the opinion expressed in your Counsel's article which appeared in these columns several years ago, and is also in accord with a resolution which has been adopted by the Radiological Society of North America, as follows:

That all roentgenograms, plates, films, negatives, photographs, tracings or other records of examinations are the property of the roentgenologist who made them or the laboratory in which they were made.

* McGarry v. J. A. Mercier Co., 262 N. W. 296.

Treatment of Tuberculosis

A young man about 23 years of age entered one of the private hospitals in the City of New York for the purpose of receiving treatment with respect to a condition that he then complained of. He came under the care of a general practitioner who was requested by a relative of the patient to take charge of the case. The physician obtained the patient's personal history and family history, which included information that certain relatives suffered from tuberculosis.

Examination led the doctor to make a tentative diagnosis of pleurisy with effusion. The doctor in an attempt to make a definite diagnosis of the case had sputum analysis and urinalysis made as well as x-rays taken of the patient's chest, all of which were negative for tuberculosis although the doctor felt the case was actually one of tuberculosis. He called another physician into consultation concerning the case and it was determined that the patient should be treated as a case of tuberculosis and the patient was kept at the hospital for some weeks where he received complete rest in bed. He was placed on the roof sun porch daily. The patient was not informed of the precise nature of his condition but his relatives were so informed.

The patient left the hospital contrary to the doctor's orders, returning to his home much sooner than was requested and at his home the doctor continued to see him frequently over a period of about a month. During that time the patient was kept in bed and remained there until his temperature became normal. The doctor then told the patient that he must be very careful of his condition and was sent to the mountains for absolute rest. The patient thereupon went to the mountains and the next thing the doctor heard from him was a few weeks later when the patient came into his office for examination. The patient was found to be in a satisfactory condition and was advised to again return to the country for rest, and to take things easy and to keep under continuous observation.

The occasions that the doctor saw the patient became less frequent, but the patient's condition when observed by the doctor seemed to be satisfactory. During that period of time various sputum tests were made and various fluoroscopic examinations were made, all of which were negative for a definite diagnosis of tuberculosis. The patient was repeatedly advised to be careful not to over work and to get as much rest as possible. Sometime later, after a period of approximately a year had elapsed since the doctor had last seen the

patient, he again called at his office and the doctor then found the patient to be suffering from hoarseness, running a temperature and showing what seemed to be definite signs of tuberculosis. The doctor did not continue to treat him however, and he went under the care of another doctor who treated him for a period of about a year and a half for an active condition of tuberculosis; the patient at the end of that time was apparently cured.

A malpractice action was brought against the doctor who had treated the patient since the original confinement in the hospital. The claim was made that the doctor failed to make a timely diagnosis of tuberculosis and that the doctor had improperly advised the patient to engage in strenuous work and strenuous exercise as a result of which it was claimed the patient was obliged to undergo an extended period of treatment in an endeavor to be cured.

The case came on for trial before a judge and jury and at the conclusion of all the testimony the issues were submitted to the jury and a verdict of no cause of action was returned in favor of the doctor.

Facial Paresis Following Mastoidotomy

A physician who specialized in ear, nose and throat work, in the course of his service on the staff of a hospital clinic, had his attention called to a young woman whose condition had been diagnosed as acute bilateral suppurative mastoiditis. She was referred to him for consultation only. He examined her and concurred in the diagnosis, and the same day another physician associated with the staff of the same hospital performed the operation, which was successfully performed, and which established the accuracy of the diagnosis. The patient remained in the hospital for about ten days and after her discharge received treatment at the clinic. About five weeks after the operation a slight facial paresis was observed.

Nearly three years after the operation was performed the patient brought an action against the physician who was called into consultation, charging him with having personally performed the operation and charging him with having negligently cut the plaintiff's facial nerve during the operation, and also charging him with having given her false and improper advice subsequent to the operation.

An application was made to the Court for a judgment dismissing the action on the ground that the acts complained of took place more than two years prior to the com-

mencement of the action. The motion was opposed on behalf of the plaintiff on the theory that the defendant had given false and fraudulent advice to the plaintiff after the operation and that, therefore, the Statute of Limitations did not begin to become effective until two years after that advice was given the patient. The Court, however, determined that the date of the operation complained of was the controlling date and directed judgment in favor of the defendant dismissing the complaint.

Fracture of Elbow

A physician who specialized in surgery was called by another doctor to attend a nine year old girl at a hospital. He found her suffering from an injury to her left elbow which she had received while skating. Upon examination he made a diagnosis of supracondylar fracture of the left humerus near the joint with dislocation of both the radius and ulna, with considerable swelling. X-rays confirmed the diagnosis. The doctor explained to the child's father the difficult nature of the fracture and obtained his consent to reduction under general anesthesia. The doctor obtained satisfactory alignment by such manual reduction and applied a plastic cast with the arm in semiflexion. An x-ray after the reduction showed almost complete reduction of the lateral displacement and partial reduction of the backward displacement. The patient remained in the hospital for about ten days with instructions to return to the doctor later. He saw her about two weeks later, removed the cast, and found the arm had present callus formation with slight

limitation of flexion and extension. X-rays were taken at about that time which showed the coronoid process was coming into contact with the lower end of the humerus after a 90° flexion. According to the doctor the child's parents were advised that an open operation might be necessary but advised them to wait at that time and to continue with baking and physiotherapy. The patient, however, was never brought back to the doctor for any further care.

A malpractice action was brought on behalf of the child in which it was charged that the defendant had been negligent in his care and had permitted a deformity to result. The case came on for trial before a Judge and jury and the plaintiff's parents testified that instead of discussing the proposition of an open operation with them the defendant had summarily dismissed them, assuring them there was nothing further he could do for the arm and refusing to name another physician to whom they might consult. After the case had been on trial for sometime and certain witnesses in addition to child's parents had testified, but no doctor had appeared as an expert witness on behalf of the plaintiff, plaintiff's counsel requested the Court to grant a delay until additional witnesses could be called. The Judge directed that he would allow plaintiff's counsel a reasonable time to produce such witnesses and when no such witnesses were put on the stand the Court granted the defendant's motion to dismiss the complaint. Plaintiff took an appeal from the judgment entered in favor of the doctor but did not take the necessary steps to bring on the said appeal for hearing. A motion to dismiss the appeal was thereupon granted, finally terminating the matter in favor of the doctor.

A "FORTUNE" IN MAKING BAD BREATHS GOOD

It seems to the *New York Times* that "opportunity beckons" in *The Journal of the American Medical Association*. The "specifications for the making of a fortune," it adds, are given there in an article written by Drs. Howard W. Haggard and Leon H. Greenberg of Yale's laboratory of applied physiology.

The doctors have been studying bad breath. They convinced themselves after much experimenting that it is usually purely local in origin. At any rate, there can be no doubt that the strong odor of garlic and onions comes from the mouth. Minute bits of the vegetables lodge between the teeth, in pockets and on the

papillae at the base of the tongue, decompose and thus give off odors.

Having satisfied themselves on this point, the doctors experimented with the better known washes. Good for no more than fifteen or twenty minutes, they found. Soap and water proved to be no better.

At last they hit on chloramine, which can be brought in any drug store. They brush the teeth and washed the mouth with Dakin's solution, made by dissolving a 4.6-grain tablet of chloramine in a little water. Even powerful garlic yielded, not for fifteen minutes but for good and all.

"The chlorine liberated in the mouth reacts chemically with the essential oils and deodorizes them," is the explanation given.

Across the Desk

PSYCHIATRIC RESCUE WORK IN THE PRISONS—If there is any place where the psyche needs a physician it is the prison. True, many would put the mental hospital first, but there the mental disorder of the patient is already recognized, while in the prison the quirks of the convict's character and disposition are sometimes so cleverly disguised as to baffle the keenest scrutiny.

It is only within the past few years, it is surprising to note, that serious effort at psychiatric work has been made in the Federal penitentiaries. The psychiatric service, a part of the medical service, was organized in 1931, when the medical work was taken over by the U S Public Health Service. Each prison now has a psychiatrist and a psychologist, assisted by inmate clerical help. Their aim is to straighten out the twists and gnarls in the convicts' psychology and adjust him mentally to live and work in peace and harmony with society when he comes out from behind the bars. Many long and high-sounding names are given to these unfortunates, but Dr. Meninger in *"The Human Mind,"* dismisses such terms as "psychopathic personality" and describes them simply as "perverse." And that is what they are, declares Warden H. C. Hill, of the U S Northeastern Penitentiary at Lewisburg, Pa. "They are headed cross stream, playing at the game, but breaking all the rules," he says, with a slight mixture of metaphor. "Their defectiveness is in their emotional functioning, and they simply cannot keep out of trouble. They may achieve some good in the world, but the world pays dearly for it and the net total of their lives is 'in the red'."

The interesting account of what is being done to set these straying and stumbling feet upon the straight path comes as a result of a radio talk on psychiatry given a few weeks ago under the auspices of the Medical Information Bureau of the New York Academy of Medicine. Radio listeners wrote in for more information about the psychiatric work for Federal prisoners, and a query sent to Washington brings a sheaf of printed reports telling all about it.

Gone are the days when a prison was just a place to lock up criminals and keep them from preying on society for a certain number of years. Now the expert psychiatric work of "ministering to a soul diseased" begins as soon as the man is inside the walls. New prisoners are kept in a kind of quarantine for thirty days before being assigned to their regular quarters and work, and

during that time they are subjected not only to a searching health examination, but also to thorough psychological and psychiatric investigations.

Of course the work is new and we must not expect too much from it as yet, but a beginning is something. These tests of body, mind, and character determine where the convict shall be located, his companions, his work, and, in short, the whole complexion of his prison life. And the examination never ends while he is there. The psychiatrist has him under constant observation and if his regimen is not working out favorably, the prescription is changed, exactly as Dr. Brown does, in the case of Jim Robinson or Susie Doolittle. When a convict breaks the prison rules and comes under discipline, the psychiatrist is there on the run, trying to readjust the motivation that has gone awry, just as the surgeon sets the broken bone. The hardened old criminal is pretty far past any psychiatric help but the new offender, eager to regain his lost place in the world, offers a promising opportunity.

We think at once of the doctor's sensitive finger tips going over the patient, pressing here, tapping there, as we read of the psychiatrists' insistent questions about the convict's past life, all his diseases, his mental disturbances, convulsions, dreams, work habits, social adjustments and maladjustment, memories, delusions, drug and alcoholic addiction, and a hundred other things. Every item goes into a record, which grows steadily year by year, and when the convict leaves, it passes into the hands of the parole officer, whose duty it is to help the man go straight in his new freedom among his fellows.

Like a huge sifter, the psychiatric tests that are going on all the time, year in and year out, in our Federal penitentiaries, sort out the psychotic cases, the drug addicts and the feeble-minded and send them to special institutions. Then the borderline psychopathic individuals, the psychoneurotic, and the emotionally unstable are separated for special treatment, the hardened habitual criminals are segregated from the general prison population and the rest are analyzed and classified for vocational guidance and occupational placement. No one claims that the work is perfect. Borderland mental deviates should have a special institution fitted for their treatment and a larger force of psychiatrists and psychologists is needed if justice is to be done.

to individual cases. Now it is necessary to ask all the prison officials to assist in the work, of which they have no adequate knowledge or training.

Experts say that the abnormal psychopathic element of the prison population amounts to roughly 15 per cent of the total. Of these, the vicious mental defectives are a frequent source of trouble, often having psychotic periods requiring hospitalization. The docile mental defective is a less serious problem, but is easily led astray. The constitutional psychopathic inferior group provides the greatest disciplinary problem of all. Their boastful attitudes and egotism are well known. Prison life brings them into mental conflicts, intolerable situations, and mental disturbances. Hospitalization, with rest and quiet, usually restores the equilibrium. The sneaking introvert types are tricky, and get what they want by putting others up to mischief while they keep in the background. Then there are the paranoid cases, the panicky victims of fears, the borderline defectives, and the assorted antisocial characters of all types.

Here is certainly a fascinating work for the physician interested in psychiatric problems. How important is it at present? It must be admitted that it is in its infancy, but it is bound to have important developments. "Now," says an Assistant Director of the U. S. Bureau of Prisons, "it is not uncommon to find the professional staff sitting lightly upon the institution organization like the foam upon a glass of beer, adding considerably to its appearance, but quickly blown aside whenever there is serious work to be done." Any such situation, however, is contrary to the ideas of the Bureau. The policy of the Bureau, we are told, "is to imbue every warden, every civilian with the idea that the primary function of the institution is to reeducate and rehabilitate the inmate." In this work the psychiatrist must be the key man.

No one can even glance over the programs of the current medical meetings without reading there as clear as daylight the growing interest in psychiatry, and not the least intriguing part of the picture is the splendid effort of the psychiatrist to take the twisted and trampled soul of the criminal in his skillful fingers and reshape it into the semblance of manhood.

Preventive psychiatric work needed. How much better, however, if the psychic snarls could be untangled before the unfortunate man or woman becomes a candidate for the jail or the mental hospital! That is what is urged by the New York State Department of Mental Hygiene. It would have mental hygiene taught in the schools and

colleges, along with physical hygiene. Physical hygiene has been part of the public school course for a half a century and has been a marvelous aid to health. Now mental hygiene is knocking at the door, and some of our best schools have admitted it to their classrooms. Instructors trained to teach it are few as yet, but they would no doubt multiply to meet a demand. Many physicians, now taking up the study of psychiatry, could well assist in this work.

The associate editor of the *Mental Hygiene News* suggests an outline of instruction. "The general anatomy and physiology of the nervous system and its relation to other parts of the body and to the mind and the special senses could be taught," says Horatio M. Pollock, Ph.D. Then might follow a study of mental habits that make for efficiency or inefficiency, as attention or day-dreaming, mental vigor or listlessness. It is easy to distinguish the habits that make for mental health or ill-health. It is but a step from this to an analysis of the mind of the individual child. Does he take a keen interest in his school studies, athletics, societies? Is his thought clear or foggy? Does he welcome or avoid work?

If the answers are unsatisfactory, it is evident that the probe must go deeper. The child may be mentally or morally weak, or be suffering from defective special senses, from physical defect, vicious environment, or mental conflicts. Anything of this sort should be discovered and, if possible, corrected.

It is not impossible, either, that the school itself may be partly to blame for the bad mental habits of the pupils. Dawdling along may be the style in certain classrooms, and when that is the case, the teacher and the school should be investigated. Some teachers are declared to be virtually carriers of mental disease, and some schools literally centers of contagion. If the teacher is aroused to active interest in the mental health and vigor of the pupils, such an unfortunate situation should soon right itself.

As the twig is bent, the tree's inclined, and local medical societies, with the growing interest in psychiatry, may well encourage this movement to take the kinks out of the twigs. The child-mind, we are also told, is "wax to receive and marble to retain," and it will be far easier to shape the mind in this tender period than to attempt it later in the penitentiary stage.

Among the many current papers on psychiatry is one read before the Louisiana State Medical Society by Dr. T. J. Perkins of Simmesport, La., on "The Importance of Mental Hygiene to the Medical Practi-

tioner" Dr Perkins notes that there were 70,000 new admissions to the mental hospitals in this country in 1933, and he asks, "Where are the 70,000 who will be admitted this year, or the 140,000 to be admitted in two years, or the 350,000 to be admitted in five years, or the 700,000 to be admitted in ten years?" It is the duty of the doctor,

he believes, to detect these cases and correct them before they reach the point where hospitalization is necessary. It is here that the physician needs such a knowledge of psychology and psycho-pathology as will enable him to recognize the early symptoms of morbid mental states and apply the proper methods for relief.

REVIEWED

System of Diet Writing Including Diet Calculator, Obesity Chart, Diet Formulary, 100 Menu Prescription Forms. By William S Collens M D. New York, Form Publishing Co, [c 1933]. Cloth, \$5.00. Oblong 16mo of 142 pages.

Medical literature abounds in theoretical considerations as to whether the diabetic should have a low, medium, or high carbohydrate, protein, or fat diet. The editorial columns of the leading medical organs bemoan the rising death rate in diabetes. In the face of this not a hand is turned to save the general practitioner from having to wade through volumes of textbooks to find and copy an adequate diet for his patient.

Dr Collens in his small book has met the need of the medical man when the question arises "What shall I tell the patient?" Through a system of diets it is possible for the physician to arrive at practically any

desired combination of carbohydrate, protein, and fat. The dial reveals the skeleton of a menu, variations of which are readily accessible. It is unfortunate that some mathematical calculation is necessary and that the diet arrived at must be transcribed to another sheet. Optimum mineral, vitamin, unsaturated fatty acid, and protein contents still are left to the physician's discretion. Nevertheless, the system is a worthy step in the right direction and can be used in any case, diabetic or otherwise, requiring a measured or weighed diet.

Supplementary to the method of quantitative diet prescription is an excellent series of qualitative diets for various medical conditions as lead poisoning, peptic ulcer, nephritis, together with the essentials of the liquid, soft high residue, low-residue, alkaline, ash, acid ash diets, and low salt diets.

GEORGE E ANDERSON

Rats, Lice and History. Being a Study in Biography, which, after Twelve Preliminary Chapters Indispensable for the Preparation of the Lay Reader, Deals with the Life History of Typhus Fever by Hans Zinsser. Octavo of 301 pages. Boston, Little, Brown & Co., 1935. Cloth, \$2.75.

Dr. Zinsser has given to us, under the above title, one of the most illuminating books of recent years. With the touch of a savant in a highly specialized branch of medicine, he has linked his "fach" in striking manner with the humanistic side of the ravages of pestilence and epidemic through the centuries. With his wide knowledge of the technical facts of typhus fever and of the great plagues which have swept the earth from time immemorial, he presents a splendid brief against the folly and crime of war, contrasting the relatively few deaths from bullets and engines of war with the huge toll taken by the infectious diseases which decimate both armies and the general populace. His book is a scientific counterpart of the Rev. Norman Angell's *Great Illusion*. In his reveries the author combines science with history in a delightful style, which brings his thesis within the range of the lay mind, thus greatly augmenting the sphere of its usefulness. This is indeed a fascinating book from a scholarly mind, for which every serious reader will be grateful and from which much food for thought will be gathered.

J. M. VAN COTT

Infantile Paralysis. By George Draper, M.D. Octavo of 167 pages. New York, D. Appleton-Century Co., 1935. Cloth, \$2.00.

The author is a very pleasant writer and gives the lay reader a pretty clear idea of poliomyelitis and its prospects.

If the impression left is a bit more favorable than seems quite true, this is the right direction in which to err and may indeed be deliberate; it is an interpretation of stated facts and not misstatement.

The space given to "constitution" the reviewer would claim to be unduly large, but if one may not exploit his favorite child, why write? This reviewer cannot see its importance as great to this subject as its proportionate share of the book.

The non-professional reader will not be misled by what he reads here.

WALTER D. LUDLUM

The Autonomic Diseases or the Rheumatic Syndrome. By T. M. Rivers, M.D. Duodecimo of 299 pages. Philadelphia, Dorrance & Company [c. 1934]. Cloth, \$3.00.

The author has considered ground soil in relation to what might be termed a cross-section of the medical diseases. He has at-

tempted to correlate respectively with augmentary and inhibitory tendencies of the autonomic nervous system (as represented by the craniosacral and thoracolumbar systems) two large groups of pathological conditions: one, the so-called hypotonic type or rheumatic syndrome including rheumatoid arthritis, fibrositis, hypotension, carditis, allergy, migraine, asthma, spastic constipation, and so on; the other, the hypertonic type, including osteoarthritis, hypertension, angina, pectoris, arteriosclerosis, gastric ulcer, atonic constipation, and so on. The amines as allergens are accredited with producing many of the effects. Doctor Rivers has painted a very convincing picture of the rheumatoid syndrome.

While one may not agree with the premises and deductions, while scientific laboratory proof of the theories may not be available, the contents of this book represent a type of armchair philosophy which in the present day of nihilism is needed as well as refreshing. They portray how a thinking physician views the every-day garden variety of pathology as seen in his practice. The conclusions may be wrong; we cannot concur in many of the opinions; we are sure, however, that such thought as Doctor Rivers has given his individual patients is conducive to better practical medicine; the patient as well as the disease is considered.

GEORGE E. ANDERSON

Diabetes Mellitus and Obesity. By Garfield G. Duncan, M.D. Octavo of 215 pages. Philadelphia, Lea & Febiger, 1935. Cloth, \$2.75.

Excellent for the general practitioner and for the medical student, this small but complete volume deals with both subjects in a practical manner, omitting controversial viewpoints. It is up-to-the-minute in its information and clear in its simplicity.

Food metabolism is dealt with in detail to get a clear conception of the two major diseases discussed in the book as well as to give a rationale to their respective treatments.

The chapter on the Diagnosis of Diabetes Mellitus can be followed step by step to a proper conclusion by modern but simple methods.

The outline for ward and clinical treatment of the diabetic and his complications is an invaluable document. The practitioner will do well to study this chapter intently.

The classification of obesities and their treatment are clear and concise. Since obesity plays such an important part in relation to diabetes treatment of the obese in certain cases is excellent prophylaxis of diabetes.

S. GARSON SLO-BODKIN

**A CAMPAIGN TO REDUCE THE DEATH RATE OF
PNEUMONIA IN NEW YORK STATE**RUSSELL L. CECIL, M D, *New York City*

Pneumonia now ranks third as a cause of death in New York State. It is surpassed by heart disease and cancer, but these two conditions at least concentrate their attack chiefly on elderly people. Pneumonia picks its victims from all ages. In a climate such as our own it is probably the chief cause of death for people in the active period of life. There are approximately 12,000 deaths a year from pneumonia in New York State alone (Figs 1 and 2)*. This means that there is an annual incidence of pneumonia in the state of approximately 50,000 cases. The mortality rate is highest in infants and in the very old (Fig 3).

The great majority of pneumonias are caused by some type of pneumococcus. Lobar pneumonia might almost be called a specific infection caused by the pneumococcus, since over ninety-five per cent of cases are of pneumococcal origin (Fig 4). The streptococcus and Friedlander bacillus are responsible for a small percentage of cases, while the staphylococcus and influenza bacillus account for a still smaller proportion.

Pneumococci have been classified into thirty-two biological types. The most prevalent of these types in the etiology of pneumonia are the first three, namely, Types I, II and III. Of these, Type I is the most common, producing in most

clinics about one third of all lobar pneumonias (Fig 5). Type II ranks second, and is responsible for twenty to twenty-five per cent of all cases. Type III causes about twelve per cent of all lobar pneumonias. It is rare in the young, but very common in middle aged and elderly people.

It is evident that pneumonia is a public health problem of the first order and worthy of the most serious consideration. Up to the present time, the control of this disease has baffled the wisest of physicians and sanitarians, but there is reason to believe that we now have at our command certain agents that can be employed with conspicuous success in the treatment of this infection.

How can the modern physician actually help the pneumonia patient? There are a few things that are most essential. We can provide the patient with the best of nursing, we can supply oxygen when cyanosis develops and we can administer serum in those types of pneumonia which are amenable to serum treatment. The nursing situation is far from satisfactory. For example, the Metropolitan Life Insurance Company has found from a study of fatal cases of pneumonia among its policy holders that ten per cent of these patients were cared for by Metropolitan visiting nurses, forty per cent were treated in hospitals and the remaining fifty per cent received no skilled care of any kind (Fig 6). Good nursing is expensive, and many poor patients with

*The author is indebted to the Metropolitan Life Insurance Company for the privilege of presenting the accompanying charts.

Presented before the New York Public Health Association at Saratoga Springs, June 27, 1935.
Dr Cecil is Chairman of the subcommittee appointed by the Committee on Public Health and Medical Education of The Medical Society of the State of New York to study the pneumonia problem in New York State.

pneumonia remain at home during their illness and receive no skilled nursing care whatever.

Every patient with pneumonia who develops cyanosis should receive oxygen.

Fig. 1—12,000 Pneumonia Deaths a Year in New York State.

Fig. 2—Trend of Mortality from Pneumonia in New York State.

Fig. 3—Pneumonia Death Rates High Among Babies and Elderly Persons.

At present very few of them do receive it. Finally, and most important of all is the question of serum therapy, and it is on this phase of the question that the Pneumonia Committee proposes to concentrate its attention. The evidence now at hand as to the efficacy of Type I anti-pneumococcal serum is overwhelming. This evidence comes from experiments on animals, from clinical observations on patients, and from well-controlled statistics based on large groups of Type I patients. In Type II pneumonia, the effect of serum treatment, while not so striking as in Type I infections, is nevertheless quite definite. In Type VII, Type VIII, and Type XIV pneumonia, there is also evidence to show that serum has considerable value. The effect of serum therapy on the death rate in these various types is shown graphically in Fig. 7. These figures are based on statistics compiled from the reports of various authors in the United States. The results of serum therapy in Type I and Type II pneumonia as reported by British writers are just as favorable as those obtained in this country. The beneficial results of serum treatment are brought out even more clearly if one includes in the statistics only those patients who received serum during the first four days of their illness. In Fig. 8 it is shown that the death rate for Type I pneumonia treated during the first four days of the disease is only 9.6 per cent as compared with a death rate of 33.6 per cent for control cases. In Type II pneumonia the effects of early serum treatment are also indicated, the death rate being cut from 45.3 per cent for controls to 29.6 per cent for cases treated during the first four days of the disease.

Most of the patients who die of pneu-

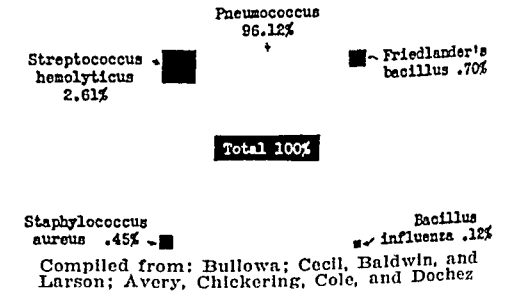

Fig. 4—Etiology of Lobar Pneumonia Among Adults.

monia die with a complicating pneumococcal bacteremia. In Fig. 9 the effect of antipneumococcal serum on patients with pneumococcal bacteremia is well brought out. In this chart it is clear that serum actually saves the lives of many patients with pneumococcal bacteremia. The death rate for Type I bacteremia cases is cut half in two. The same is true in Type VII and Type VIII infections. In Type II pneumonia the death rate is high even for serum treated bacteremic cases, but it is definitely lower than that for those who received no serum.

It should not be forgotten that antipneumococcal serum is valuable even for those patients who would recover anyway, as it usually shortens the acute stage of the disease by several days, and by so doing shortens also the duration of convalescence.

With many indications that the pneumonia problem is now amenable to attack, a campaign to reduce the death rate from this disease in New York State is being planned for the coming winter. This project is being jointly sponsored by the Medical Society of the State of New York, the New York State Department of Health, and the Metropolitan Life Insurance Company. The campaign will be conducted under the direction of an Advisory Committee consisting of representatives from these three organizations, and will be modelled roughly after the very successful pneumonia campaign which has been waged during the past five years in Massachusetts by the Commonwealth Foundation, and the Massachusetts State Department of Health.

The object of a campaign such as we

propose to carry out should be two-fold:

1. To reduce the incidence of pneumonia.
2. To provide better treatment for patients with the disease.

Unfortunately, reduction of the incidence of pneumonia is a tremendous problem in itself, and one which offers little hope of solution with the agents now at our command. While it is true that pneumococcus vaccine induces an efficient immunity in both animals and man, the protection afforded is of only a few months' duration. As a matter of fact, the incidence of pneumonia in American troops was definitely reduced during the World War by the use of pneumococcus vaccine, but here military discipline made possible the application of methods that would probably be impractical in civil life.

It is a common observation that both lobar and bronchial pneumonia are nearly always sequels of the milder forms of respiratory infection, chiefly influenza and the common cold. In the opinion of the writer, the ultimate control of pneumonia is closely tied up with the control of grip and coryza, and until we have a clearer understanding of these infections, the prevention of pneumonia by public health measures must remain an unsolved problem. The most that we can do is to stress to the layman the importance of taking proper care of a cold in the head, and of preventing its transmission to one's family and associates by isolation of the patient and by recourse to other well-recognized hygienic measures.

The second objective of the Committee is to provide better treatment for the patient with pneumonia, and it is toward this goal that most of its attention will be directed. There is every reason to believe that if the medical profession and the lay public of New York State can be sufficiently aroused to the importance of this problem, and if they will cooperate in the various measures proposed, a very definite reduction can be made in the death rate from certain types of pneumonia.

The Committee's immediate program is:

1. Dissemination of knowledge concerning the cause, nature and treatment of pneumonia.
2. A closer tie-up of physicians with the diagnostic laboratories of the New York State Department of

Health.

3. The facilitation of prompt nursing care and of efficient serum treatment in pneumonia.

A wide dissemination of knowledge concerning the pneumonia problem is, we believe, one of the most important functions of the Committee. This information will be spread in three directions: to *physicians*, *nurses*, and the *public*.

To *physicians* we will attempt to bring a gist of the large amount of knowledge that has been obtained by laboratory and clinical investigators during the past two decades concerning the etiology and treatment of pneumonia. In the opinion of the writer, there are several phases of the problem that should be particularly stressed to the practitioner. They are, early clinical diagnosis, early bacteriological diagnosis, and the prompt use of serum and oxygen therapy in suitable cases. Every physician of course is familiar with the classical signs of pneumonia, but if we are to make prompt use of oxygen and serum therapy, we must establish a diagnosis of pneumonia *before* the typical signs make their appearance; in other words, before complete consolidation of the affected lobe takes place. The modern diagnosis of pneumonia is made from the history and from the early symptoms and signs, such as chill, fever, pain in the side, cough, and the expectoration of pink or rusty sputum.

We also want every practicing physician to know that a bacteriological diagnosis, or "typing," on a case of pneumonia can now be made very quickly,—often in an hour or two—and that even in those exceptional cases in which sputum is lacking, the pneumococcal type can usually be determined promptly by using mucus from the throat, or in twelve to eighteen hours by means of cultures from throat swabs, or perhaps from blood cultures.

Finally, we wish to familiarize the family physician with the newer methods of serum and oxygen therapy, and to impress upon him the importance of using these agents early in the disease before the infection spreads and bacteremia develops. With the concentrated and refined products now in use, the serum therapy of pneumonia has become a fairly simple matter. We hope to hasten the day therefore when practically every

cise of pneumonia will be typed, and serum given to all patients who need it.

We propose to gain the interest and enthusiasm of physicians in this subject through various channels. THE NEW YORK STATE JOURNAL OF MEDICINE provides a medium in which our Committee can present various phases of the pneumonia problem from time to time during the winter months. In addition to medical articles and reprints, we are planning to have the subject of pneumonia presented by eminent speakers to every county society in the state.

Scientific exhibits have become a very popular method of presenting medical topics, and justly so, for by means of such exhibits a great deal of information can be absorbed in a short time. At the last meeting of the Medical Society of the State of New York in Albany, a pneumonia exhibit was presented under the auspices of the Committee on Public Health and Medical Education of the State Society, and the Metropolitan Life Insurance Company. This exhibit, consisting almost entirely of charts, created considerable interest, and was shown again this fall at the Annual Graduate Fortnight of the New York Academy of Medicine. The Pneumonia Commission of Massachusetts is also making use of an exhibit which has already been presented at several society meetings with great success.

Motion pictures, demonstrating the modern treatment of pneumonia, will no doubt prove of practical value, just as they have in various other phases of medical teaching. Dr. Jesse Bullowa of the Harlem Hospital, has recently prepared such a film which illustrates clearly the rapid methods of typing, allergy tests, serum therapy, etc.

The key note of this educational program for physicians should be *speed* in diagnosis, typing and treatment. Until doctors learn to treat the pneumonia patient as an *emergency* case, we will not make a very big dent in the pneumonia death rate.

Visiting nurses must be taught to recognize the early signs of pneumonia in order that the physician may be promptly summoned. Without the cooperation and advice of the visiting nurse, the patient and his family will often

mistake pneumonia for a severe cold, and medical care will be postponed until the time for efficacious treatment has passed. Nurses should also be instructed as to the proper method of collecting sputum, the early signs of allergic reactions, and the technic of running an oxygen tent.

We believe that the education of the *Public* in respect to pneumonia is just as important as the campaign for physicians and nurses. Our Committee has already put a great deal of thought on this phase of the program, and it is clear that a number of facts have to be taken into consideration. In the first place, the great majority of pneumonia cases occur in the cities. Therefore, the greater part of our effort should be directed toward educating the urban population. In the final analysis our problem must focus itself on the *individual*, that is, the individual layman. Rich or poor, he must be taught to call a physician, or go to a clinic or hospital as soon as he gets sick with a cold or cough. Unfortunately, we have no reliable figures that would tell us just what day of his disease the average patient with pneumonia is first seen by a physician, but we do have figures that indicate when these patients are first admitted to the hospital. In Fig. 10 there are some statistics based on the records of Bellevue and Harlem Hospitals. In a series of 2,670 cases of lobar pneumonia, 55.1 per cent were admitted to the hospital *after* the third day of the disease. If we allow one day for "working up" the case in the hospital, it is clear that more than one half of all pneumonia patients admitted to these two hospitals never receive any specific treatment until the fourth or fifth day of the disease, or even later.

Day	No. of Cases	Percent
ALL CASES	2670	100.0
FAST 5 DAYS	1200	44.9
AFTER 3rd DAY	1470	55.1
1st	295	11.0
2nd	455	16.2
3rd	474	17.7
4th	474	17.7
5th	370	13.9
6th	250	8.6
7th	175	6.6
8th	221	8.3

Compiled from Bellevue and Harlem Hospitals

Fig. 10—Lobar Pneumonia—Day of Morbidity When Admitted to Hospital

Treatment so late in the infection is usually too late to be effective.

Today the layman knows the significance of a chronic cough with fever. (Tuberculosis?) He must now be taught the dangers of an acute cough with fever. (Pneumonia?) The layman should also be instructed regarding what things *not* to do when he has a cold; such as, exposure to cold and wet, getting fatigued,

have been effectively employed by the Metropolitan Life Insurance Company, and are a valuable though expensive method of publicising information. Hand bills and posters attract wide attention, and have been used with great success in the campaign for vaccination against diphtheria. Such a hand bill for pneumonia has been used by the Metropolitan Life Insurance Company. (Figure 11.)

All of these mediums are available for our pneumonia propaganda, and we plan to make every possible use of them.

The second objective in the Committee's program is the development of a closer tie-up of practicing physicians with the laboratories of the New York State Department of Health, for the purpose of facilitating sputum typing, blood cultures, and any other laboratory work incidental to the diagnosis and treatment of pneumonia. As far back as 1916, the Division of Laboratories and Research of the New York State Department of Health initiated the manufacture and general distribution of Type I antipneumococcus serum, according to the methods devised by Cole and his coworkers at the Rockefeller Institute. At the same time the Division of Laboratories began to prepare and distribute diagnostic serum for Types I, II and III pneumococci. These products have been available for practitioners throughout New York State ever since that date.

In addition to the Central Laboratory in Albany, there are now one hundred twenty-eight laboratories in New York State (most of them in hospitals) which have been approved for general diagnostic service, and of these, seventy-seven have the approval of the State Commissioner for the examination of pneumonia sputum. During 1934 a total of 11,779 examinations for pneumonia were performed in State and approved laboratories.

The isolation of the new types of pneumococci (now thirty-two in all) and the discovery of rapid methods of identifying them have placed new demands on the Division of Laboratories, but these demands are being met by Dr. Wadsworth and his staff. Diagnostic sera are being prepared for all types of pneumococci, and a field bacteriologist will visit the various approved laboratories throughout

PNEUMONIA

Works Fast!

Good care at the beginning saves lives.

Delay in calling the doctor and the nurse may be fatal.
Every minute counts.

Self-prescribed medicines and the wrong kind of care often lessen chances of recovery.

Fig. 11.

loss of sleep, contact with others who have colds, etc.

With respect to methods of instructing the public, we can make use of all the usual channels for spreading information. Popular lectures and radio talks will be arranged. Already a series of popular articles on the subject of pneumonia are being prepared for publication in the daily press. This phase of the work is under the able direction of Mr. Dwight Anderson, Director of Public Relations Bureau of the Medical Society of the State of New York. Advertisements in magazines

the State and help directors organize and extend this special diagnostic service.

During the coming winter it should be possible for physicians all over New York State to have prompt, accurate and complete typing on all pneumonia patients. And they should not forget that when, as occasionally happens, no sputum can be obtained, the type can usually be determined from a throat swab, though it may take a little bit longer to make the determination by the swab method.

The third objective of the Committee will be to facilitate prompt nursing and efficient serum treatment, the latter to be achieved by supplying concentrated serum free or at a nominal cost to the physicians of New York State.

The nursing problem is one of the most difficult that the committee has to face. We believe, however, that if nothing more were accomplished by the committee than getting the patient with pneumonia under skilled nursing at an earlier date, we would have made a real step in advance. The average doctor is unacquainted with what he can have in nursing service, and the average layman is equally so. One of our jobs will be to inform both physicians and laymen concerning the service available from the Visiting Nurses' Association.

A few years ago Dr. Lloyd Felton of Harvard devised a method of concentrating and refining antipneumococcus serum. Since the publication of Felton's work, a considerable amount of investigation along similar lines has been carried out by the Division of Laboratories and Research in Albany under the direction of Dr. Augustus B. Wadsworth. As a result of these various investigations, practical methods for the concentration and refinement of antipneumococcus serum have been devised, and several of the biological manufacturers now prepare and distribute concentrated serum for both Type I and Type II pneumonia. A concentrated polyvalent serum against pneumococcus Types IV, V, VII, and VIII is being prepared by one of the biological manufacturers.

At the last session of the State Legislature, Commissioner Parran succeeded in getting a special appropriation for the manufacture of concentrated antipneu-

mococci serum by the New York State Division of Laboratories. The chief objection to the concentrated serum has been the expense attached to employing it on poor patients. This difficulty is now about to be removed. During the coming winter, any patient, rich or poor, who needs refined Type I serum can obtain it by having his physician make application for it through the proper channels. During the coming year the Division of Laboratories will focus their efforts on the preparation of concentrated Type I and Type II serum. Eventually, however, therapeutic sera will probably be available for several of the other more prevalent types.

With respect to the method of distributing serum, the Pneumonia Committee has not as yet reached any final conclusion, but it appears likely that serum will be issued to physicians by the director of the approved laboratory where the typing has been carried out. This would seem to be the simplest and most logical method of distribution.

So far nothing has been said about oxygen therapy. The cyanotic patient needs oxygen and needs it badly. Oxygen treatment by means of the tent is highly efficient, but the tents are expensive and require expert supervision. It appears probable, however, that eventually much cheaper and simpler methods of administering oxygen will be available. Oxygen, like serum, should not be postponed until the patient is as blue as indigo, but should be applied at the first indication of cyanosis and kept up thereafter without intermission until the patient's temperature reaches normal.

In conclusion, we can say that the modern serum treatment of pneumonia of certain types is practical, efficient, and almost entirely free of hazards if the necessary precautions against allergic and thermal reactions are followed.

Your Committee, in initiating this campaign, pleads for your enthusiastic cooperation. We have only one object in view, and that is a reduction in the pneumonia death rate. We can achieve that in only one way, and that is by working *with* and *through* the general practitioner.

RAYNAUD'S DISEASE: AN HYPOTHESIS AS TO ITS CAUSE

ARTHUR F. KRAETZER, M.D., *New York City*
Associate Attending Physician, Lenox Hill Hospital

While the author was associated as medical consultant with Throne, Myers, and Van Dyck in their investigation into the relationship between eczema and the retention of the heavy metals, particularly arsenic, the following hypothetical question propounded itself: for what conditions could chronic arsenic retention be a possible cause? Both Throne and Myers found arsenic in the urine of about 30 per cent of all cases of eczema. Of this group a large proportion recovered on removing the arsenic by intravenous injection of sodium thiosulphate.¹⁻⁶ In about 70 per cent of cases of infantile eczema Van Dyck found arsenic in the mothers' milk. In other words they established the widespread retention of arsenic as a fact.⁷

The presumable answer to the question stated is that chronic arsenic retention might be a possible cause in any disease of the sympathetic nervous system, the bone marrow or the liver, for all of which arsenic is a more or less specific poison. Arsphenamine-jaundice is a sufficiently frequent example of the last. As for the second, the occasional appearance of agranulocytic angina after salvarsan suggests that arsenic may conceivably be the exciting factor in that malady, even perhaps in the more frequent cases without so obvious a history.

Another suggestive fact is the slight but consistent decline in granulocytes following uncomplicated antisymphilitic treatment. The demonstrated ubiquity of arsenic retention, particularly in the United States, where such enormous quantities of lead arsenic are used so recklessly as sprays for fruits and vegetables, would seem to make such a suggestion worth following.⁸⁻¹⁰

Raynaud's disease lends itself admirably for test of application of the stated hypothesis, because of its clear definition and curious character. Lacking the elements of local infection, and having no characteristics ascribable to distant focal infection, the disease is unique. Its strange multiphasic manifestations suggest at the

very start, and with a high degree of plausibility, a drug-effect.

The first case was reported in *The Journal of the American Medical Association* for April 5, 1930.

A woman of 38, first seen October 7, 1929, reported trouble which started in February, 1929, at first limited to the terminal phalanges of the fingers but soon involving the entire length of both fingers and toes. The symptoms were classical, wax-like pallor in the cold, blackish-purple and intensely painful cyanosis on warming, with return to normal color in about a quarter of an hour. Since 1928 she had suffered from fatigue and had noticed that her perspiration had a garlic odor. Every spring since 1922 an intensely pruritic eczema would appear on the anterior surface of the wrists and last about a month. The attacks of Raynaud's disease kept up almost every day, cleared up in the spring, and recurred in October, when she came to the author.

She was first asked about her occupation. For the past three years she had done secretarial work; for fourteen years previously she had worked in a greenhouse. This led the author to conclude the problem solved, thereby betraying a deplorable and most unscientific optimism. It had been part of the woman's daily duties, year after year, to squirt Green Fly Spray over the plants, and she lived in a mist of arsenical solution.

Physical examination showed an undernourished woman who looked vaguely below par, tired and anxious. The skin of the face was tense and shiny, with numerous telangiectases, and the waxy almost atrophic appearance of the arsenic-eaters. There was a chronic itchy blepharitis, which it will be remembered, is another symptom of arsenic poisoning. The rest of the physical examination was negative.

The urine collected for twenty-four hours after intravenous injection of 1 gram of sodium thiosulphate showed .068 milligrams of arsenic per 100 grams of dried material. It was not tested for lead. The blood chemistry showed a low sodium chloride, 437.7; sugar 103.2; urea nitrogen 11.4; uric acid 1.98.

Treatment consisted of 1 gram of sodium thiosulphate intravenously twice weekly up

to February 3, 1930. During the first week of treatment the attacks were less frequent and almost lacking in pain although the color sequences were just as marked. This relief from the hitherto customary pain impressed the patient with the feeling that some profound change was taking place in her condition. Very soon another modification manifested itself. On October 19 and 25 there were attacks of local syncope changing back to normal color without the intermediate phase of asphyxia which had regularly been present.

The condition cleared up with an extraordinary swiftness a swiftness which gave reassurance in following the more tedious cases which came later. There have been no attacks whatsoever since the end of December, 1929, up to the time of this writing (February, 1934).

A fact which particularly impressed her as indicating cure was a simple experience. Whereas at times she had been able to go out in cold weather without getting an attack, she had never been able to drive a car in the cold without suffering one. The combination of cold plus gripping the wheel inevitably caused trouble. On Christmas, 1929, she drove her car in bitterly cold weather without gloves and had no attack whatsoever.

The next four cases were reported in the NEW YORK STATE JOURNAL OF MEDICINE for November 15, 1932, and are here summarized.

CASE II R. F., woman, aged 33. Attacks started in the fall of 1926 and consisted of the following series of manifestations in this order: 1. The ears turned dead white. The fingers turned pale but were not absolutely blanched. 2. The affected parts suddenly turned purplish red and there was a sense of swelling. Rubbing the parts caused itching. This lasted fifteen minutes to an hour. There was neuralgic pain which at times was intense and at times persisted after the skin had returned to normal color.

Cold seemed to precipitate the attacks, which occurred two or three times a day at first. Later on several months elapsed without an attack. Frequently during the attack there were uncomfortable sensations in the face and tongue. Constriction and a dependent position increased the pain. The woman had done a great deal of pruritus. Early in the course she took arsenic and thought that the symptoms were aggravated. In 1929 she took up gardening and used a great deal of lead arsenate. In the fall of the same year the attacks, temporarily less numerous, resumed their original

frequency and severity. The author first saw her in August, 1930.

Physical examination was negative except for chronic tonsillitis, chronic blepharitis, and dermatographia. The urine was negative. Complete blood-count was normal except for a mild anemia. The Wassermann was negative. The blood chemistry showed sugar 86.8, sodium chloride 441.8, urea nitrogen 13, uric acid 3.12. The urine collected twenty-four hours after intravenous thiosulphate showed .093 milligrams of arsenic per 100 grams of dried material, and 3 milligrams of lead in 1,000 cc.

Treatment was started August 9, 1930 and consisted of 5 grams of sodium thiosulphate intravenously twice a week. The following summary describes the course of the case: August 14—No swelling or redness. Slight aching in toes and fingers. August 18—Feels better generally. August 21—Tingling and some pain but no color change. Weather cooler. August 25—No finger symptoms. Tongue slightly sore. Feels stronger. August 29—No symptoms. September 1—No symptoms except slight burning of tongue. September 6—No symptoms. September 11—No symptoms. September 20—Fingers red and swollen on rising with slight aching pain instead of the severe and longer lasting pain that usually occurred. September 29—No symptoms. October 1—Weather quite cool. This morning very slight swelling and redness of fingers of left hand alone with very little pain. October 6—No symptoms. November 6—For past two weeks fingers have been numb on exposure to cold but without pain, swelling, or color change. This morning a characteristic attack, but mild and short lived. Patient is convinced that there has been definite improvement. December 4—No symptoms for the past four weeks in spite of exposure to severe cold. January 5, 1931—Mild attack, the first in the past two months. February 9—Free from symptoms. January 4, 1932—The patient had one slight attack on this date but with this exception passed through the winter without trouble.

There has been no recurrence up to the winter of 1934.

CASE III H. E., woman, aged 43, was first seen October 19, 1931. Her complaint was that every winter for three years, especially while driving a car, one or two fingers would turn dead white and tingle severely. On warming they would return to normal color without an intermediate phase of asphyxia. She had suffered from pruritus for seventeen years. At some time in the past she had been given two courses of

iron and arsenic injections. Two quantitative Marsh tests on the urine after thio-sulphate injection showed, one a trace of arsenic, the other .035 milligrams per 100 grams dried material. No lead was present. From October 19, 1931, to January 8, 1932, she was given two intravenous injections of thiosulphate a week. Improvement set in from the start. During this period, instead of the usual frequent attacks, there was but one and that merely the whitening of the tip of one finger on rising one cold morning. On January 8, 1932, she reported occasional slight tingling of fingers without color change while driving her car in the cold. She was discharged clinically as cured, and there has been no recurrence up to the winter of 1934. Incidentally the winter itch cleared up likewise.

CASE IV. E. M., woman, aged 25. First seen February 11, 1931. There was a history of taking tonics. Complaint: for two years, fatigue, anorexia, and inability to stand the cold. In March, 1930, just after coming in from outdoors, the terminal phalanges of the third and fourth fingers of the right hand turned dead white for a few minutes and then a deep red for a few minutes, finally resuming their natural color. There was no unusual sensation. The next attack occurred in the summer of 1930 while swimming. The terminal and middle phalanges of the right middle finger turned dead white with a sharp line of demarcation at the base. This lasted about five minutes and was accompanied by a sense of numbness. The two phalanges then turned a deep purplish red with a sense of tingling and burning but no real pain. This also lasted a few minutes and seemed to be brought to an end by vigorously shaking the hand.

Physical examination was negative except for the general appearance of fatigue and being generally below par. Poor peripheral circulation was indicated by the presence of marked livedo and acroasphyxia. The urine collected twenty-four hours after intravenous thiosulphate showed no lead but .154 milligrams of arsenic per 100 grams of dried material. She was able to take but two injections of thiosulphate but took it regularly in capsule form, five grains three times a day. On March 3, 1931, she reported that on stepping into a hot bath after a long walk in the cold, she noticed a tingling sensation in the soles with marked pallor. The color soon returned to normal without any intermediate stage of asphyxia. She said that after a month of thiosulphate by mouth she was feeling much stronger. In March, 1932, she reports that she had no

attacks though she went in swimming and was exposed to the cold. The general condition was greatly improved.

The attacks in this case were of course too mild and too infrequent to derive any conclusions as to the effect of treatment upon them. It is, however, not without significance that in this patient's case, as in the rest, arsenic was found in the urine and the general health improved greatly under thiosulphate.

CASE V. A. M., male, aged 30. First seen April, 1921. His complaint was fatigue. In 1913 in South America he had a penile sore which, without any investigation by dark-field or Wassermann, was treated with three injections of arsphenamine and ten of mercury.

Examination was negative except for coated tongue blepharitis, a mild secondary anemia and moderate acrocyanosis. In no significance of the last-named finding suggested itself.

By way of a thorough measure, iron and arsenic were prescribed, which the patient took for several weeks. From April 1921, to February, 1932, he was under careful observation for lues, but all findings, physical, blood, and spinal fluid have been negative.

Though not sick he has never felt very well. In May, 1931, he complained of increased fatigue and a sense of tingling in the feet and head. On a cold day the terminal phalanx of the right forefinger turned dark purple and felt numb. The feet felt numb and were very sensitive to cold. Tobacco seemed to intensify the sense of tingling. Intravenous thiosulphate was started May 7, 1931, but only a few injections were given. The urine showed .268 milligrams of arsenic per 100 grams of dried material. It was not tested for lead. The following notes were taken: *March 11, 1931*—The tingling had left the feet. It had left the hands temporarily and then returned in lesser degree. Still present in left temporal region and tended to shift over the scalp. *March 14*—Tingling markedly diminished. *May 18*—No tingling. Violaceous color of face less marked. *May 21*—No tingling. *May 30*—After prolonged swim, left index finger turned dead white for fifteen minutes and then returned to normal without asphyxia or paresthesia. Patient was free from symptoms until January, 1932, when there was a return of the tingling and sense of fatigue. Syncope of the terminal phalanx occurred once on a cold day. All symptoms responded promptly to thiosulphate.

As in Case IV, the Raynaud symptoms were too mild and too infrequent to base any direct conclusions upon. The association with these mild symptoms, however, of severe paresthesia, marked fatigue, plus a large amount of arsenic in the urine, capped by the clearing up under thiosulphate, certainly suggest that all the symptoms can be grouped under a common etiological head. It is possible that in this case an element of peripheral neuritis was present.

The following was first reported at a meeting of the Manhattan General Hospital.

CASE VI. C. P., an Italian woman of poverty-stricken surroundings, age 33, first consulted the author in April, 1932. From the age of fourteen to nineteen she worked at varnishing pencils, all colors of varnish being used. From nineteen to twenty she worked in a watch factory. Her trouble started in 1920, right after her marriage. Exposure to cold would bring on a slight pallor of the tip of the right forefinger. The condition gradually became more frequent and more severe. In the fall of 1928, shortly after the birth of a child, the trouble rapidly grew worse and in a few months involved all the fingers of both hands with the typical sequence of syncope and numbness in the cold and asphyxia on warming. The right index finger, the original site of the trouble, was always intensely painful during the asphyxial stage. The attacks were particularly severe and frequent during the winter, averaging three or four a day, but she never missed an attack even in the summer, when a damp day or washing clothes or dishes would inevitably precipitate one. It would take about an hour for the color to return to normal. Her husband was under treatment for syphilis and one child was highly suspicious for hereditary lues, though never was there any definite evidence of the disease detected in her. The physical examination was negative except for chronic tonsillitis, a healed apical pleurisy, and a probable mild hypothyroidism.

The urine before intravenous thiosulphate showed .018 milligrams of arsenic per 100 grams of dried material, a negligible amount. Twenty-four hours after thiosulphate the arsenic excretion jumped to .751 milligrams, an enormous amount, the contrast between before and after thiosulphate showing an extreme degree of retention. The lead in the urine was .065 milligrams per 1,000 c.c. before thiosulphate and .039 milligrams nine days later, after four thiosulphates had been given.

Treatment was started on April 25, 1932, and consisted of two intravenous injections per week of .5 gram thiosulphate. Within less than four weeks definite changes were manifest. The attacks were less frequent and when present were free from pain. She was frequently able to wash clothes and dishes without an attack of even color change, something which she had never been able to do before even in hot weather. From July 25, to October 20, 1932, treatment was interrupted by a therapeutic abortion and a stormy convalescence. On October 15, she had a severe attack with asphyxia and pain, the first recurrence of these symptoms in five months. For about a month prior to this attack she had been taking a tonic nostrum containing iron, copper, zinc, phosphorus, and manganese. From then on up to the time of this writing she has been treated in a more or less desultory way, her treatment being interrupted by various vicissitudes at home. The last painful attack occurred December 5, 1932. The condition has progressively improved, although she still (February, 1934) has occasional attacks of pallor. However, in spite of its being an exceptionally cold winter, the attacks are limited to two or three attacks of syncope of a few phalanges per week, without asphyxia and without pain and lasting from a few seconds to ten minutes, as against three or four daily attacks of all the fingers with asphyxia and severe pain and lasting an hour. Furthermore, she is no longer in dread of handling water. It is disappointing not to have been able to eliminate even these minor attacks of syncope after so long and tedious a course, but the improvement is unequivocal.

CASE VII. B. P., woman, aged 37, came under observation January 5, 1934. Her trouble started about 1924 with syncope of one finger, increasing in frequency and extent until several fingers of one or both hands were involved on going out into the cold. The attacks now show the following sequence: (1) Sense of cold; (2) numbness; (3) syncope; (4) aching pain; (5) deep purplish asphyxia with burning pain which frequently is severe enough to make her cry; (6) redness; (7) normal color. The pain may last half an hour and it usually takes that length of time for the fingers to return to normal color after going into a warm room. Driving a car always aggravates the attacks. The physical examination was negative. The urine showed .096 milligrams of arsenic before thiosulphate and .068 milligrams of lead twenty-four hours after thiosulphate. As a result of a mistake in the laboratory the usual procedure was missed.

The following is the course of the case: *January 5, 1934*—Thiosulphate No. 1. *January 12*—Very cold weather. Severe painful attack of five fingers. *January 15*—Thiosulphate No. 2. Very slight attack of pallor. *January 16*—Two slight attacks of pallor. No pain. *January 17*—No attack in spite of being out in cold. Appetite greatly improved. *January 18*—Thiosulphate No. 3. After prolonged exposure to cold, slight pallor of balls of two fingers, lasting but a few minutes. Slight burning on warming but no pain or asphyxia. Since first thiosulphate has had but one attack (*January 12*) with asphyxia and pain. All others limited to slight syncope returning to normal after a few minutes in a warm room. *January 22*—Thiosulphate No. 4. No attack since *January 18*. Slight attack this evening after long walk in cold; five fingers white five to ten minutes; no pain, burning, or asphyxia. *January 23*—No attack. *January 24*—Thiosulphate No. 5. Slight pallor of three fingers after long walk in cold, followed by almost imperceptible mottled, not solid, asphyxia, returning to normal in a few minutes without pain or burning. *January 29*—Thiosulphate No. 6. No attack until this day. Weather bitterly cold. Two attacks of syncope of ten fingers with tingling and return to normal in a very few minutes without pain or asphyxia. At night, after standing half an hour in intense cold, very severe attack like the usual former ones but not lasting so long; pallor for one-half hour with severe pain for fifteen minutes. *January 30*—One attack of slight pallor with prompt return to normal. *January 31*—No attack. Out all day. *February 1*—No attack. *February 2*—No attack despite prolonged exposure to cold. Patient remarked what Case VI also noted, that for a few hours after an injection of thiosulphate there was an increased tendency toward attacks followed by a definite cessation. This is probably explained by the increased mobilization of arsenic deposited immediately after thiosulphate. *February 3*—Out all day in cold. Slight pallor of two phalanges in evening, lasting five minutes. *February 4*—No attack. *February 5*—Very slight pallor of two phalanges lasting two or three minutes. *February 6*—Thiosulphate No. 7. Slight indefinite pallor of three fingers clearing in two or three minutes. No pain for a week. Constant exposure to severe cold. Feels better generally. *February 6 to February 16*—Occasional slight pallor. *February 16*—Thiosulphate No. 8. Marked pallor followed by faint cyanosis without pain on going out into severe cold one-half hour after injection. *February 19*—Thiosulphate No. 9.

Slight pallor this evening. No other attack since *February 16*, despite exposure to bitterly cold weather.

This case is still under treatment. Nine injections of thiosulphate in seven weeks—a highly insufficient amount, by the way—have changed the picture from one with three to four severe daily attacks, with asphyxia and intense pain, to one with about three incomplete and short-lived attacks per week of pallor with neither pain nor asphyxia.

A few technical points may be brought out here. Presence of arsenic in the urine before thiosulphate may be of no practical significance. It may simply represent the normal elimination of recently acquired arsenic in people able to excrete it. Absence of arsenic before the first thiosulphate, followed by presence of arsenic within twenty-four hours after thiosulphate, is of very decided significance, for it shows the existence of an arsenic-retention. Thiosulphate should be given intravenously twice a week in doses of .5 gram freshly prepared from highly purified crystals. Solutions already made up in ampoules are not so reliable. The material used in these cases was Sulfactol (Metz).

In their long series of eczema cases Throne and Myers have shown that after a considerable series of injections, improvement may stop and there may even be a regression. They have found that this is associated with an alkalosis and during this phase excretion of arsenic ceases. This refractory state is corrected by a few intravenous injections of calcium salts, whereupon thiosulphate may be resumed. This curious fact may have some bearing on the mysterious question as to why some people retain arsenic and get into trouble, whereas others excrete it immediately following its intake.

Another interesting point brought out by Throne and Myers is the change in the blood chemistry when metallic retention is present. Using the Hastings-McLean technic for blood-sugar determination, they consider anything above 100 milligrams per 100 c.c. to be high, and call particular attention to the sodium chloride-sugar ratio. On this basis the ratio is normally five to one. In cases of metallic retention it approaches four to one, the sugar being raised and the sodium chloride being lowered. In addition, the urea-nitrogen tends to be low. Presumably

these changes are due to impairment, respectively, of the glycogenic and urea-forming functions of the liver. There are occasional cases of chronic metallic retention where there is no shift of the sodium chloride-sugar ratio toward four to one, but when this shift is present a metallic retention can be predicted with considerable certainty.

Summary

Seven cases of Raynaud's disease treated with sodium thiosulphate are presented, six female, one male.

Case I Severe Duration nine months. Urine after thiosulphate showed 068 milligrams of arsenic. Not tested for arsenic before thiosulphate. Not tested for lead. Treated ten weeks. Clinically cured. No recurrence in five years.

Case II Severe Duration four years. Urine after thiosulphate showed 093 milligrams of arsenic and 3 milligrams of lead. Not tested before thiosulphate. Treated eighteen months. Clinically cured. No recurrence in two years.

Case III Moderate Duration three years. Urine after thiosulphate showed 035 milligrams of arsenic and no lead. Not tested before thiosulphate. Treated three months. Clinically cured. No recurrence in two years.

Case IV Mild Duration one year. Urine after thiosulphate showed 154 milligrams of arsenic and no lead. Not tested before thiosulphate. Treated for several months with thiosulphate by mouth, only two intravenous injections. One slight recurrence in March, 1931. No further recurrence in three years.

Case V Mild Duration one month. Urine after thiosulphate showed 268 milligrams of arsenic. Not tested for lead. Treated for one month. No recurrence in three years. The only male case in the series.

Case VI Severe Duration twelve years. Urine showed 018 milligrams of arsenic before thiosulphate and 751 milligrams within twenty-four hours after. Lead present before and after thiosulphate. Treated irregularly for twenty-two months. Marked improvement. Still has minor attacks of pallor, but no pain or asphyxia for over a year.

Case VII Severe Duration ten years. Urine showed large amounts of arsenic

and lead. Treated irregularly for past seven weeks and still under care. Marked improvement. Attacks now limited to less frequent, less severe and much shorter episodes of pallor, with no asphyxia or pain.

All of these cases showed a marked improvement in general health.

A Note On Definition

Just what is Raynaud's disease? Some would deny that mere syncope of a single terminal phalanx would justify the diagnosis. Other even more rigorous believers in the written word would insist that it is not Raynaud's disease unless it conforms to its so called synonym, symmetrical gangrene of the extremities. The generally accepted view, however, is that the cases herein reported fall under the author's heading. The fact that in these cases the first symptom was syncope, to be followed months or years later by the classical series of events, including asphyxia and pain, would obviously point to the difference being merely a matter of degree. This is most emphatically borne out by the fact that as the cases progressed toward recovery, the last symptoms to appear, asphyxia and pain, were the first to clear up.

Conclusion

It is a risky thing to draw conclusions from the *post hoc propter hoc* argument of "before and after taking." The path to hell is paved with undistributed middles as well as with good intentions. But the unbroken sequence of seven cases of the triplex coincidence of Raynaud's disease, presence of arsenic and cure or marked improvement on removing the arsenic, would certainly suggest that the thesis of this article is justifiable at least as a working hypothesis. Three common factors repeated seven times in a row should seem to amount to something. Some may raise the objection that in all the hundreds of thousands of people who have received salvarsan, no case of Raynaud's disease has been reported. The reply to this is that it is pentavalent arsenic which has the greater tendency to be retained in the body. Trivalent arsenic which is what composes salvarsan, is much more readily eliminated.

Doubtless certain constitutional elements play a part. Of these most certainly sex is one, for Raynaud's disease is much more prevalent among women than among men. And there may well be others. The doctrine of the parsimony of

causes falls down in the field of pathology. But whatever complex aggregate of factors is involved in Raynaud's disease, it is suggested that arsenic—or at times, possibly, lead—is the *sine qua non*.

THE GLAND PRODUCT CRAZE

No group of pharmaceutical preparations in recent years, perhaps, has been the subject of such extravagant claims, remarks Dr. Morton S. Biskind, of Chicago, in the *A. M. A. Journal*, as that comprising allegedly active materials derived from various glands, nonglandular organs, and body fluids. Hardly a tissue or fluid of the body has escaped desiccation or extraction; substances so obtained are marketed in pills, tablets, capsules, vials and ampules for introduction into the body by every conceivable route.

Only a small percentage of the many preparations are known to contain active material; and with the few exceptions (thyroid, liver, stomach, adrenal cortex and some estrogenic principles) the products administered by mouth have little effect even if they do contain some active principle or principles. The active substances are either destroyed by the digestive juices or, if not broken down, they may not be absorbed from the intestine. Thus, glandular therapy by the oral route is in general quite limited; even when effective it is usually wasteful, as much more material must be used owing to poor absorption. However, when dealing with relatively impure products that may have toxic effects on parenteral injection, it may be preferable to administer the preparation orally, if feasible. An example of this is adrenal cortex extract. Purification, particularly important

for preparations intended for parenteral use, involves many difficulties.

Assay involves still further difficulties. The majority of methods employed are biologic; the effect of a given preparation is determined on some physiologic function in a test animal. At best biologic assay entails very large errors. Much confusion arises from the present deplorable state of endocrinologic nomenclature; this is particularly true with respect to commercial products. Not infrequently the physician is confronted with a series of products purporting to be similar but sold under widely different names or with other products unquestionably different but marketed under similar names.

The author describes various commercial glandular products, mentioning well known substances described in the U. S. Pharmacopeia or in New and Nonofficial Remedies briefly or not at all. Emphasis is placed on the more important products marketed in the United States. He concludes that clinical applications of many of the newer commercial glandular products are on a very unsatisfactory basis. Physicians, particularly those who do not have facilities for controlled clinical observation, would do well to be guided by the judgment of the Council on Pharmacy and Chemistry in the use of these products. The advertising propaganda of pharmaceutical manufacturers cannot be depended on as a safe guide in this respect.

CANCER OF THE BREAST

JOHN J. MORTON, M.D., *Rochester*
and
SAMUEL J. STABINS, M.D., *Rochester*

We have studied the case histories on the 180 malignant tumors of the breast admitted to the Strong Memorial and the Rochester Municipal Hospitals from 1926 to 1934. Radical operation was performed on eighty of these patients; palliative operation on fourteen. Of these eighty-six were so advanced that operation was not considered. These patients were given palliation whenever possible by radiation or drug therapy. During the same period of time, there was operative removal of ninety-two benign tumors of the breast. These records were also reviewed. Two groups of patients with lesions in the breast have not been assembled as it was difficult to trace them. These include the unquestionably benign growths, which were not operated upon; and the patients who presented themselves for examination for a supposed lump in the breast which could not be located on examination. These two latter groups make up a fairly good number of patients. They present a difficult problem to the physician as he must assume a grave responsibility. Repeated examinations at stated intervals should be insisted upon and carefully conducted in this class of patients so that early lesions may not be overlooked.

The age incidence for malignant tumors of the breast follows in general that for malignancy elsewhere. The majority of patients fall in the 40 to 70 age period. There are always in any series exceptions which prove interesting. In our cases, there were eight patients with cancer of the breast who were under 40 years of age; viz., 29, 30, 33, 33, 34, 36, 38, and 38, respectively. There were also three above 70, a Christian Scientist of 78, for whom a radical operation was performed, and two other women with breast cancer at 81 and 84 years, respectively.

The male sex is by no means immune to tumors of the breast. In our group, there were two patients with cancer, both of whom also had syphilis; and nine

benign tumors, the commonest of which was fibroadenoma, five times. Cancer, in the male in our experience, here and elsewhere, is always a serious condition. It should be relatively easy to find these tumors early but the spread seems to be rapid even when the tumor is small.

In regard to etiology we will not enter into a discussion of the factors supposed to have a bearing such as lactation, stagnation, and so forth. We have been much interested, however, in the frequency with which trauma has been mentioned by our patients with breast tumors. Trauma to the breast cannot be very uncommon in women. The breast, struck against some object with sufficient violence to be recalled, was a possible cause for the swelling in fifteen cases of malignant tumors; and in eight cases of benign growths. The relation of trauma to breast cancer only assumes etiologic importance from the fact that it may have a medicolegal bearing. In two of our patients with malignant breast tumors, the claim was made that the breast was injured when the patient was thrown against the seat of a trolley car.

No student of the cancer problem today assumes a single etiologic factor to be operating in any neoplastic disease. There is always the hereditary predisposition, about the mechanism of which even the geneticists are not in agreement. And there are time factors and repeated irritation factors, misplaced cell rests, endocrine imbalances, and so forth, all of which may have a bearing.

In order to establish that a single trauma has even a contributory relationship it is necessary to prove, *first*, that a sufficiently severe trauma actually occurred (one patient said that she had bleeding from the nipple following trauma); *second*, that the breast was normal before or immediately at the time of the accident; *third*, that the localization of the neoplasm be reasonably close to

the injured area; *fourth*, that a proper time interval elapse between the time of the accident and the development of the new growth; *fifth*, that the histology of the tumor conforms to the time relationship, i.e., a slow growing tumor which appears in a very short time after the injury or a rapidly growing tumor which appears after a long time would not seem logically to have any connection with the trauma. Furthermore, a tumor such as a dermoid cyst would at once be recognized as a congenital defect.

It is obviously almost impossible to fulfill these conditions in any given case. Experimentally, also, it has never been possible to produce a cancer by a single trauma. There is even evidence that single traumas may favorably affect a growth by damaging the blood supply but any such supposed advantage is more than offset by the danger of metastasis. It has been experimentally proved that rough handling or massage of malignant tumors is followed by generalization in a high percentage of cases.

In the examination of the breast for a suspected tumor it is advantageous for every physician to work out a method which will be thorough. It is our practice to have the patient strip to the waist so that both breasts can be inspected at the same time. With the patient sitting upright, a careful inspection is made for differences in the contour of the breasts. The level of the nipples is contrasted on the two sides. Increased vascularity or inflammation over any area is noted. The nipple on one side may be retracted; or fissured; or there may be signs of caked secretion indicating discharge. A visible tumor is occasionally seen bulging in some part of the breast; and definite dimpling or thinning out of the skin may give evidence of underlying trouble.

The patient is then asked to recline on the examining table with both arms above the head. This allows excellent observation of the axillae and it may also bring out puckering in the skin over a tumor. Palpation is then carried out, the normal breast being examined first in order to determine the normal for the individual in question. The flat of the hand is used to gently feel over the whole breast. Then, by moving the fingers alternating up and down as in using a typewriter, the breast

is covered in smaller zones. The normal breast having been palpated and its characteristics noted in the mind of the examiner, the examination of the involved side is then conducted in the same fashion. The nipple zone and areola are not examined till last as palpation in these areas may set up engorgement in other zones of breast tissue. The axillae and the supraclavicular regions are also given careful attention, especially the glands low on the jugular under the insertion of the sternomastoid tendons.

In some individuals with heavy breasts the only way to detect a small mass is by palpating the breast tissue through small areas by gently feeling the edges between the thumb above and the fingers below. If a tumor is made out its characteristics should be determined. This includes the contour, smooth or irregular; the consistency, hard, semielastic, soft; the fixation, freely movable, relatively fixed, so that the skin or nipple is retracted on moving the tumor or on lifting the breast below it; or absolutely fixed, so that the whole breast is anchored at some point. Fibroadenomas, for example, can be diagnosed by their mobility. These tumors feel smooth, elastic, and slip away from the examiner, often moving several centimeters. This characteristic makes it difficult to remove them under local anesthesia unless measures are taken to secure them in position in some way under the procainized skin. The tense cysts of fibrocystic disease will also seem to move on the underlying chest wall, but if the lesion is fixed on either side, it is seen to be the movement of the breast itself and not the tumor.

Of course, it is needless to emphasize the general thorough history and physical examination when a tumor is palpated and a radical operation may be contemplated. The history should be sure to cover such points as headache, backache, neuritis pains, cough, and so forth. The physical examination should include a hemoglobin and red-cell count. Roentgenograms of the chest should always be taken under such circumstances.

If patients with cancer of the breast were coming to us in the ideal earliest stages, no one would be able to make a diagnosis without looking at the tumor. All such cases would have to be subjected

to operation and the diagnosis would rest on the gross or microscopic picture of the tissue involved. Unfortunately, we rarely, as yet have had this Utopian dream realized. In a general surgical clinic such as we have, the diagnosis of the nature of the tumor of the breast can, with few exceptions, still be made by the ordinary methods of physical examination. The earliest cases we see give a history of accidental discovery of a painless nodule. On examination, it proves to be hard, irregular, and shows dimpling or increased vascularity of the skin over it.

The newer methods of transillumination, soft roentgen ray pictures of the breast, and breast skin prints have helped us confirm our clinical diagnosis in many instances. But in the doubtful cases they have misled us as often as they have helped. Transmission of light through a tumor does not always mean that it is cystic. In fact it has been embarrassing to demonstrate to medical students transmission of light through two tumors, which clinically we all believed were solid, and to assure the class that this meant tense cysts, only to find them solid fibroadenomas on removal. In two other cases we have been influenced to do radical operations on benign lesions because soft tissue roentgen ray examinations were reported as cancer. Possibly in time, these methods of examination may be worked out so that they may be of help. It is certain, however, that they will never supplant the information which must be gained only through physical examination. At the present, in our hands they are useful as supplemental examinations, and in no way surpass the clinical estimation of the nature of the process.

At this point it might be well to call attention to the fact that physicians connected with the large hospitals are constantly missing opportunities to do good preventive medicine for their patients. The routine examination of the breast is either not done at all or in such a perfunctory manner as to be worthless. The records bristle with long descriptions of heart and lung sounds which often mean nothing to the life of the patient, whereas, a nodule overlooked in the breast may lead to the most serious consequences. This failure to examine the breasts may represent a hangover from the Victorian

age when such things were to be approached with great embarrassment to all concerned. The failure to make this examination is not confined to any one service because all services fail equally in it. *It should be a rule that no female patient over 35 years of age should be discharged from any hospital until a routine examination of the breasts has been made and recorded.*

There have been some examples in our series where tumors, both benign and malignant, were discovered within a short time after the patient had left a hospital where a thorough examination should have been done. Human nature being such as it is, it is futile to expect that women are going to have periodic examinations for cancer of the breast or elsewhere. The only hope for getting early lesions is by taking advantage of the chances offered, until some dictator can make such examinations compulsory after a certain age.

In the average hospital case of cancer of the breast which comes to operation, the surgeon can be reasonably sure of his diagnosis from the history of growth in size, and so forth.

It has been considered necessary by the operating surgeon to cut down on the tumor for inspection or removal in only eight of our cancers of the breast. In seven of these the diagnosis of cancer was made correctly on gross examination alone; and in the eighth case it was considered probable cancer. Frozen section confirmed this diagnosis and was used in but two of the other cases to bolster the surgeon's judgment of his gross diagnosis.

In the case of the benign tumors more mistakes have been made but fortunately in the right direction. Some cases have presented such outspoken malignant characteristics on examination that radical operation has been done without question. There have been six cases with single, large, hard, irregular masses fixed to the skin or nipple which have been considered cancer clinically and have had radical operations performed. The fixed sections showed them to be chronic cystic mastitis in two instances; fibroadenoma in two cases, one in a man with inflammatory fixation of the skin; a peculiar acute and chronic inflammation with giant cells in

one case; and lipoma of the breast with pig skin appearance, fixation and a visible hard lump in another case.'

In one case an exploration was done, the tissue removed, and frozen section diagnosis of cancer was made. When the fixed sections were obtained there was marked papillary cystadenomatous change in a chronic cystic mastitis.

In two instances, the roentgen ray diagnosis so supported the belief of the clinician that he did a radical for intracanalicular fibroadenoma and chronic cystic mastitis, respectively—large single masses with signs classed as malignant. In one last instance, biopsy was suggested by the attending surgeon as the lesion was doubtful but a radical was performed by the operator for adenoma of the breast.

These ten cases indicate that diagnosis cannot always be certain even in the presence of attachment to the skin, dimpling, retraction of the nipple, and firm irregular masses. Several other in-

stances of similar clinical conditions were recognized by biopsy of the involved area before proceeding with the radical operation which was thus avoided.

In only three instances have we done simple mastectomy where the lesion was clinically benign but pathologically suspicious on fixed section. In one an intracystic papilloma had invaded the basement membrane, and in two others there were suspicious cellular areas. When a frozen section or gross examination is doubtful we do not do a radical operation as it has been our experience that fixed sections in these cases are generally benign.

It is our practice in lesions of the breast to excise the suspected area with a margin of normal tissue, not seeing the tumor at any point if possible. Then the excised tissue is cut open by the surgeon and a gross inspection made. In almost every instance it is possible to make a diagnosis in this manner if the surgeon is familiar with the pathology of the breast as he

CHART

The operations for malignant and for benign breast tumors are indicated in this chart. More patients with benign lesions are seeking advice than formerly.

Operations U. of R. Hospitals

should be. If the lesion is benign the operation is thus finished by simple closure of the incision. If the tumor is malignant there is not the same danger of squeezing out malignant tissue juice and cells from the incision, even though closed, in the manipulations necessary to remove the breast radically. We have had no experience with needle or punch biopsies. Perhaps these methods would save a few unnecessary radical operations if they were used indiscriminately in all breast tumors. These procedures do not appeal to us for the small doubtful cases where in such instances a negative report would not be convincing.

We do not propose to discuss here the pathological picture in cancer of the breast. There are many interesting questions still to be solved such as the sweat gland cancers and sweat gland epithelium in breast tumors. It is well to know that these pale cells do occur and that their origin is in debate. We have the feeling from observing our cases that scirrhus carcinomata are not so well held in check as the more cellular types. We look upon them as very treacherous types of lesion when once they have escaped from the local area. We have been very much interested in the rather frequent association of cancer and chronic cystic mastitis in our cases. In eight instances this has been striking in the gross and microscopic examinations. We believe that this indicates that a woman who has bilateral chronic cystic mastitis should be carefully followed by her physician from time to time, and not dismissed. It is our conviction that she is just as likely as any other woman to have a cancer arise in her breast.

We think that women are coming to the doctor more often for lumps in the breast than they were ten years ago. A

chart of our operations for benign and malignant tumors indicates that this is so because we now operate on more benign than malignant tumors and the reverse was true previously. (See Chart.)

In treatment we believe that the results are not so good that one can afford to neglect anything which may help combat this disease. There can be no compromise with cancer. If the tumor is operable we favor radical operation to be followed by radiation. We do not believe in pre-operative radiation as a general principle for several reasons. It leads to unnecessary delay in getting rid of the focus of disease. It often makes the patient sick and in poorer shape to stand the operative procedure later. It definitely hurts the morale of a good many patients who are worried and discouraged because the growth does not disappear. And it exposes a certain number of patients to unnecessary inconvenience and expense because they do not have cancer, although the clinical diagnosis has been such. Two of our benign tumor patients for whom radical operation was done had previously been subjected to a course of preoperative radiation. In two other instances the benign character of the lesion was recognized after a course of radiation and relief was obtained by removal of the benign tumor.

We radiate our patients postoperatively and follow them up as closely as we can though we still lose track of some. If the case seems favorable for cure we push radiation to its effective limit. If the patient seems to have a hopeless prognosis, it is not good medicine to take away her comfort by useless therapy.

It would be of the greatest value if some clinic would run a series of patients under the conditions as we see them today without any radiation at all. The end

TABLE

	Probable malignancy	Now living	Now dead	Cannot trace	Outspoken malignancy	Now living	Now dead	Cannot trace	Biopsy or palliative op only
1926	1	1	—	—	4	—	4	—	3
1927	3	2	1	—	9	4	5	—	3
1928	1	1	—	—	8	2	3	3	—

Totals	18	16	1	1	76	32	31	11	17

results might show just exactly what radiation contributes to this problem. We believe that surgery and radiation can give a much higher percentage of arrest of cancer than they have, if the patients can be seen before they are outspoken cases of cancer. The accompanying table shows a marked difference in the results when operation and radiation have been used for cases which were probable cancer as compared to that obtained when there was no doubt about it.

Conclusion

There is a surgical principle which applies to ulcerating and infected breast cases. It is the same principle which we use in amputations when there is infection in the limb. It is just as important to leave the breast wide open without any attempt at closure when there is an infected area in it as it is to do a guillotine amputation when there is infection in the tissues below.

18 AUDUBON STREET

"MEDICAL BUREAUS" THAT EXPLOIT THE POOR

Instead of the spirit of helpfulness that should inspire everyone during hard times, it is peculiarly shocking to find people willing to lower themselves and their professions by exploiting the poor. So remarks Dr. Morris S. Bender, President of the Queens County Medical Society, in an interesting article in the *Long Island Press* (Jamaica). What rouses this caustic remark is "the so-called medical bureau," owned and controlled by lay individuals. The plan of these lay bureaus is to maintain solicitors and canvassers who enroll groups and families at an average charge of 10 cents per week per person. This amounts to from \$5 to \$7 per year per family.

For this fee the subscriber is entitled to nothing except a pamphlet which lists an enrollment of physicians with this medical service bureau. These physicians receive no compensation and are to render medical service free of charge.

Now, here's the catch. Their reward for service rendered is obtained through the sale of medications which they carry in their kit. Each sale amounts to approximately one dollar. All surgical or obstetrical work or any cuts or bruises treated must be paid for, even though no medication is furnished.

Picture a doctor in this modern day as a walking drug store, giving you exactly what you need in the event of any illness. Medical service bureaus bear no responsibility except the raking in of enormous sums from the gullible public.

The doctors who enroll in the medical service bureaus unfortunately are compelled to do so by circumstances, often by lack of medical patronage because of the competition of just such service bureaus.

The quality of the physician rendering this service may be very good and frequently is bad. However, if a doctor is good to begin with, it does not take long for him to deteriorate when he has to work

for nothing. There is a definite economic law that services rendered are worth exactly what they cost.

Through legal technicalities, among which is the usual incorporation as a business bureau instead of a medical bureau, these frauds continue to operate from year to year. They cannot properly care for the sick under their set-up and operate only at a terrible expense to the poor.

Doctors worthy of the name will not debauch themselves or cheat the people they serve by listing themselves in such a roster as the medical bureaus. As a matter of fact, any physician affiliated with the bureaus in question is barred from membership in the American Medical Association and the State and County Medical Societies.

People should carefully investigate the merits of these bureaus. Then they should remember that their health demands attention more than their pocketbooks, for without the health, the pocketbook will suffer.

These so-called service bureaus have been a blot on the State and City Health Departments and upon the profession for many years. There are two ways of eliminating them—by legislation and by the public's refusal to patronize them. Medical societies are doing their best to have the bureaus outlawed legally. It is up to the public to help force them out by making it unprofitable for them to operate.

The substance contained in liver which is responsible for its effectiveness in the treatment of pernicious anemia has been announced isolated by Dr. H. D. Dakin and Dr. Randolph West, at Presbyterian Hospital in New York City.

The substance, described as "appearing to be proteid in character" is obtained from liver extract through the use of a highly specialized process of precipitation. It has already been used clinically at the hospital, and many cases responded "markedly."

ACOUSTIC NEURINOMAS IN THE STAGE OF NORMAL INTRACRANIAL PRESSURE

An Analysis of Thirteen Early and Late Cases

WALLACE B. HAMBY, M.D., *Buffalo*

In his monograph of 1917, Cushing¹ outlined the sequence of symptoms caused by acoustic tumors. The symptoms in the average case occur more or less in the following stages: (1) the auditory and labyrinthine manifestations; (2) the occipitofrontal pains with suboccipital discomforts; (3) the in-co-ordination and instability of cerebellar origin; (4) the evidences of involvement of adjacent cerebral nerves; (5) the indications of an increase in intracranial tension with a choked disc and its consequences; (6) dysarthria, dysphagia, and finally cerebellar crises and respiratory difficulties. Little has been added to the knowledge in general of the symptomatology of these tumors since this statement was made, but that knowledge has been diffused among the profession so that the lesion is being recognized more frequently in the stages preceding increased intracranial pressure. In discussing the mortality rate of operations upon these lesions, Cushing expressed the hope that in the future we might see these patients operated upon at a period at least two years earlier, on the first signs of general pressure symptoms, lessening postoperative morbidity as well as mortality rate.

In his report he presented case histories of thirty patients, all of whom exhibited signs of increased intracranial pressure. Great numbers of individual cases have been reported since that time, and in a later publication Cushing² listed one hundred and fifty other cases of the lesion from his series of operations. There has appeared no report of the incidence of early cases in a series of recent operations for acoustic neurinomas.

In a series collected between 1930 and 1935 were sixteen cases of acoustic neurinoma. Three of these were diagnosed

clinically as bilateral acoustic neurinomas and were not operated upon; they were omitted from the studies. The remaining thirteen cases were histologically verified acoustic neurinomas, or perineural fibroblastomas of the eighth cranial nerve. Other cerebello-pontine angle tumors, gliomas, meningiomas, etc., were also excluded. Eight of these patients had increased intracranial pressure, four were operated upon in the stages preceding intracranial pressure, and one (5) was a borderline case. The criteria of increased pressure used in making this separation of cases were: (1) choked disc; (2) measured spinal fluid pressure exceeding 200 mm. of water; (3) the presence of hydrocephalus detected by encephalography or ventriculography; (4) evidence of increased intracranial pressure obtained by ventricle puncture at the time of operation. The borderline case mentioned had a spinal fluid pressure of 200 mm. of water and the ventricles were not drained at encephalography because of a foramenal block, but ventricle puncture did not show the ventricle to be dilated, nor was the fluid under increased tension. In the analysis it has been included in the group preceding increased intracranial pressure. For convenience of description these patients have been divided into two groups (Tables 1 and 2): Group I, those with no increase in intracranial pressure, and Group II, those with increased intracranial pressure.

Since the lesion develops within the substance of the acoustic nerve and grows without early destruction of its fibers, irritative phenomena of either the cochlear or vestibular division usually are noticed early in the anamnesis. Theoretically, the earlier the stage in which the tumor is found, the shorter should be the

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 14, 1935. These cases are presented through the kindness of Dr. W. Jas. Gardner from his service at the Cleveland Clinic, Cleveland, O.

TABLE I.—INITIAL SYMPTOMS AND CRITERIA OF CLASSIFICATION INTO GROUPS.

(1) Bilateral hyperactive response.

(2) Bilateral atypical response.

Group I—Patients with normal intracranial pressure. Group II—Patients with increased intracranial pressure.

symptom history. Actually this is influenced greatly by variations in the speed of growth of the individual lesions (Table 1). One tumor (2), only 1 cm. in diameter, had caused tinnitus for eight years and deafness for five years with no increase in intracranial pressure, while another (10), measuring 1.5 x 2.5 cm. had caused vertigo for only seven months, but was accompanied by papilledema and hydrocephalus. In general, the larger tumors were found associated with increased pressure, but in one case (1), the tumor had reached the size of 4 x 6 cm. without causing increased pressure.

Duration of Symptoms: (Table I) The average duration of all symptoms in the group with normal pressure was three years and nine months, while that of those with increased pressure was slightly less than two years. This may indicate that the more rapidly growing lesions cause earlier incidence of increased intracranial pressure, or it may be that in the presence of increased pressure the patient's memory for the dates of development of symptoms is not so accurate. In view of the carefully detailed histories obtainable from many of the latter group, the first explanation seems more logical.

Initial Symptoms: It was found that vertigo was the most frequently noticed "first symptom," initiating the symptom complex in two of the five cases in Group I, and in four of the eight cases in Group II. Tinnitus was the initial symptom in one of each group.

Involvement of the Cranial Nerves

Acoustic Nerve: (a) Vestibular Division: Acoustic neurinomas are believed by many to originate within the vestibular nerve in the majority of cases. As noted above, vertigo was the most frequent symptom ushering in the syndrome. Objectively, ataxia of greater or lesser degree was found in all cases of both groups. Nystagmus was present in all but one case (10), a late one of rapid progression. The nystagmus was of a slow, coarse, horizontal type, increasing in amplitude on rotation of the eyes toward the side of the lesion.

Caloric Vestibular Tests: One of the most characteristic of all findings in cases of acoustic neurinoma is loss of the vestibular

responses on the side of the lesion when the ear is douched with hot or cold water. This test is particularly valuable since it usually differentiates tumors of the nerve itself from those of the cerebello-pontine angle or of the cerebellum. However, as has been noted by others, some vestibular fibers may persist unimpaired in the periphery of the lesion and transmit a reaction when stimulated. Of the five Group I cases, four gave no response to caloric stimulation on the side of the lesion, the reaction of the so-called "dead labyrinth." The other case (5) gave *hyperactive* responses on both sides. Of seven Group II cases tested, four gave no response on the side of the lesion; one (9) gave a sluggish response; one (11) gave a slightly atypical response, and one (13) had sluggish response on each side. While the absence of a caloric response in one ear is one of the most constant findings, failure to find a "dead labyrinth" does not always exclude the diagnosis of acoustic neurinoma.

(b) Cochlear Division: Tinnitus, an irritation phenomenon of the cochlear division, is to be expected early in the course of the disease, but only one of five cases in Group I and two of eight cases in Group II mentioned it as an initial symptom. Tinnitus usually yields to deafness in the ear and in most cases precedes the onset of deafness. In one Group I case (4), however, tinnitus did not appear until the ear had been known to be partially deaf for four years. Tinnitus was present in three of four Group I cases and in four of eight Group II cases. Often it is of short duration at the onset of the disease and may be forgotten by a careless patient if it be of mild degree. Unilateral partial or complete deafness was known to have been present in four of five Group I cases, and in five of seven Group II cases. In all cases of both Groups, some degree of unilateral deafness was found on testing.

Involvement of the Adjacent Cranial Nerves

(Table II.) All of the cranial nerves finally may be involved when the tumor has reached sufficient size to produce a marked hydrocephalus, but those of the posterior fossa are subject to early direct pressure or traction effects. The proximity of the facial and trigeminal nerves make these two particularly vulnerable. The trigeminal gives evidence of disturbance earlier than the facial, and one may

find the facial nerve so stretched over the surface of the tumor as to be almost unrecognizable on inspection, in patients who have exhibited no demonstrable signs of facial weakness.

Trigeminal Nerve: Three of the five Group I cases had noticed numbness of the same side of the face and one (1) had suffered such pain that two operations had been performed for supposed trigeminal neuralgia. Of the eight Group II cases, only two (12 and 13) complained of facial numbness. The most sensitive test for impairment of function of this nerve is that for corneal sensation. This was lost or greatly impaired in all five of the cases in Group I and in six of the eight cases in Group II; in two cases (7 and 10) no note had been made of the reaction.

Abducens Nerve: Involvement of this nerve is rarely by direct pressure of an acoustic tumor, but is produced either by the pressure of high intracranial tension or by strangulation of the nerve by an overlying blood vessel.⁴ Diplopia was noticed in one (4) Group I and one (13) Group II case, and objective ipsilateral abducens palsy in only two Group II cases.

Facial Nerve: Three of the five cases in Group I and three of the cases in Group II showed evidence of unilateral facial palsy. This was never severe in degree, was seen generally only on retraction of the lips and was not noticeable with the face in repose. The most typical finding was an "ironing-out" of the nasolabial fold when the patient smiled.

Glossopharyngeal, Vagus, Accessory and Hypoglossal Nerves: Examinations of the functions of this group of nerves were not recorded with sufficient uniformity to allow accurate separation of findings in this group of nerves and the vocal cords were not routinely examined. Dysarthria and dysphagia were present in two of the five Group I and in none of the cases in Group II.

Pain or Tenderness: Local pain and tenderness to pressure over the mastoid tip or the suboccipital region on the side of the lesion was present in three of the five Group I cases and in three of the Group II cases. In the records of the other five Group II cases no note had been made concerning this finding, but it is our impression that it occurs very frequently in these patients. In one case

(13) local pain was the initial symptom.

Lumbar Punctures: Lumbar punctures (Table 1) were done in four of the five Group I cases and in four of the eight cases of Group II. Gardner,³ using kymograph tracings of the spinal fluid pressure to record the effect of unilateral jugular compression, has reported three cases showing positive Tobey-Queckenstedt phenomena on the side of the lesion. It has been our practice to make no compression of the jugulars in the presence of a spinal fluid pressure of 250 mm. or more of water, so the test was not applied routinely to the Group II cases. In one case (12) with a pressure of 450 mm., it was found that only a slow fall of pressure followed removal of fluid, indicating patency of the fluid passages. The pressure was slowly lowered to 150, after which the Tobey-Queckenstedt test was made, and a venous block was indicated on the side of the tumor. Evidence of venous block was found in none of the four cases of Group I.

The only significant findings on analysis of the spinal fluid was the increase of globulin content (Pandy test) in two of the four Group I cases and in all four of the Group II cases in which the fluid was analyzed. These fluids contained increased quantities of total protein in all cases. This is in agreement with the recent findings of Hare.⁵

X-ray: Roentgenographic evidence of erosion of the petrous portion of the temporal bone or of widening of the porus acusticus was present in one of the four Group I cases and in one of the four cases of Group II.

Summary

An analysis was made of thirteen cases of acoustic neurinoma verified at operation between 1930 and 1935. Three other patients with bilateral tumors were not operated upon and were omitted from the analysis. Of the thirteen cases, five were found to have no increase in the intracranial pressure, and in eight cases the pressure was increased. It is believed that this proportion of cases without increased pressure consulting the neurological surgeon is greater now than in past years and is probably due to the wider recognition of the diagnostic syndrome by the profession. The separation of cases into

groups by anatomical phenomena does not correspond to the duration of the patients' symptoms; the average duration of symptoms of the group without increased pressure was three years and nine months, while that of those with increased pressure was slightly less than two years. Apparently the discrepancy is to be accounted for by differences in the speed of growth of the lesion, the more rapidly growing tumors causing increased intracranial pressure earlier than do the more slowly growing ones where the brain is able to become adjusted to the presence of the new growth.

Unilateral absence of vestibular response to caloric stimulation is perhaps the most useful criterion for the separation of patients with tumor prior to the advent of increased intracranial pressure

from the large number of patients exhibiting signs of vestibular and cochlear irritation and pareses. 333 LINWOOD AVE.

NEW STATE TUBERCULOSIS PATHOLOGIST

Max Pinner, M.D., formerly of the Desert Sanatorium, Tucson, Arizona, has recently been appointed principal diagnostic pathologist for the state tuberculosis hospitals.

Doctor Pinner received his medical education at the Universities of Berlin and Tübingen, Germany, and has postgraduate training in the field of experimental, pathological, and clinical tuberculosis in Hamburg. Before going to Tucson, Doctor Pinner was engaged in research in tuberculosis at the Municipal Tuberculosis Sana-

torium in Chicago during which time he was an instructor at the University of Illinois Medical School. Later he was director of laboratories of the Maybury Sanatorium, Northville, Michigan, and pathologist at the Herman Kiefer Hospital in Detroit.

Doctor Pinner's scientific contributions have dealt principally with the bacteriological, serological, immunological, and pathological phases of tuberculosis work. His headquarters will be at the Biggs Memorial Hospital, Ithaca.

AIR-CONDITIONED AMBULANCES

Air-conditioned ambulances are shortly to bring greater safety and comfort to New York's ill and injured.

Following an earlier announcement that custom-made weather for motorists has reached the stage of engineering reality, the president of a large New York company operating private ambulances has made known that installation of the first of these motor-car air-conditioning units will be in one of the ten ultra-modern "hospital rooms on wheels" which his concern operates in Manhattan, Brooklyn, the Bronx and London, England.

"Invalid transportation offers the most advantageous of fields for application of automotive air-conditioning," he said. "Invaluable medical advantages and practical

comforts will accrue to the sick from controlled atmosphere in ambulances.

"They can be moved in a moderate temperature in summer and kept comfortable and uniformly warm in winter. They will breathe only the purest of purified air, filtered and humidified or dehumidified. By keeping the windows closed at all times, the air will be kept constantly and completely clean within, even when it is dirtiest without."

The Medical Record gives this formula for industrial remedy research: Find an attractive name; 2, discover a medicine to fit the name; 3, discover a disease the medicine will remedy; 4, advertise like hell; 5, count the profits. Success!

THE MODIFIED MIKULICZ OPERATION AS OPPOSED TO THE ONE-STAGE PROCEDURE FOR CARCINOMA OF THE COLON

C. V. BURT, A.B., M.D., *New York City*

*Instructor in Surgery, New York Post Graduate Medical School and Hospital,
Columbia University*

Carcinomatous tumors of the right half of the colon are usually large, bulky, ulcerating growths, which do not tend to encircle the bowel, and hence do not often produce obstructive signs.

The right half of the colon arises, in common with the small intestine, from the midgut. The function of the right half, like the small intestine, is primarily absorptive, and hence symptoms from tumors in this region are chiefly those of deranged physiologic function. That is, that carcinoma of the right half of the colon produces greater anemia and general debilitation than that of the left, which is thought to be due to the greater absorption of toxins through the richer vascular and lymphatic radicles of this region.

The malignant tumors of the left half of the colon are small, encircling fibro-carcinomata which reduce the lumina to a small calibre and hence produce mild obstructive phenomena in a majority of instances.

The left half of the colon originates from the hind-gut and its function is principally that of storage. Its wall becomes progressively thicker, its lumen smaller, its contents more solid, and its vascular and lymphatic supply less abundant than that of the right.

It is, therefore, clear that symptoms from these tumors in the left half of the colon result principally from obstruction.

Selection of Operation

The selection of an operative procedure for carcinoma of the colon depends primarily upon the location of the tumor, the degree of obstruction, the evidence of metastasis, the amount of infection and inflammatory reaction around the growth, and the obese or asthenic condition of the patient. Personal or economic considerations should play no part whatever in the selection of the operative procedure.

Even in the presence of metastatic lesions in the liver and retroperitoneal structures, it is often advisable to remove the primary tumor mass, for these patients handle the metastatic lesions better than they do the primary tumor. Their intestinal obstruction is relieved, and they are thus given a more comfortable existence than would be possible in the presence of the original tumor.

Carcinoma of the right half of the colon indicates a primary ileocolostomy between the terminal ileum and the transverse colon, preferably of the end to side, aseptic type. In patients with good general resistance the tumor may be resected and the operation completed in one stage, or, in less favorable cases, the extirpation of the growth may be deferred to a later date.

The modified Mikulicz operation is occasionally employed in resection of tumors of the right half of the colon. The principal disadvantage is that it allows the escape of the excoriating liquid contents of the ilium, which markedly irritates the surrounding skin.

Carcinoma of the lower sigmoid, recto-sigmoid, and rectum usually indicates an abdominoperineal resection in one or two stages.

Occlusive, malignant tumors of the left half of the colon are generally more safely treated by the so-called "obstructive resection" or modified Mikulicz procedure.

In referring to the Mikulicz operation, I refer to the modified form as it is generally used today, rather than as first practiced by Bloch in 1892, by Paul in 1895, and popularized by Mikulicz in 1903.

The original Mikulicz operation entailed simply the mobilization of the segment of gut containing the tumor and bringing it out through the incision, without any attempt to remove the adjacent gland bearing tissues of the mesentery.

From the Surgical Service, New York Post Graduate Hospital. Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 14, 1935

This procedure has been modified in recent years to include the removal of a triangle of mesentery containing the lymphatic structures immediately adjacent to the tumor, and into which metastasis would primarily take place.

The modified Mikulicz operation is most valuable and finds its principal indication in tumors of the splenic flexure and more particularly in the sigmoid loop.

The principal objection to the old Mikulicz operation is the high incidence of transplantation of carcinoma cells into the abdominal wound. This is easily understood when one considers that the corresponding lymphatic structures of the mesentery were not removed, but were simply fixed into the wound. This objection does not apply to the present modification of this procedure. With the resection of the tumor and its immediate metastatic zone of mesentery, the persistence or so-called recurrence of carcinoma in the wound or region of anastomosis should be no higher than that of resection of the same tumor with

primary anastomosis and closure of the abdominal wound. In other words, this operation as it is modified today permits as radical removal of a tumor as can be

Fig. 2 The tumor has been isolated and the Rankin clamps applied. The peritoneal edges are being approximated.

Fig. 1. The lateral peritoneal reflection has been incised and the sigmoidal vessels have been ligated at the root of the mesentery. The dotted lines indicate the extent of excision of the tumor, with its metastatic zone of mesentery.

Fig. 3. The tumor with adjacent intestine has been cut away with the cautery. The retroperitoneal space has been closed, and the limbs of the colostomy apposed with interrupted sutures.

done by any other procedure, affords a lower mortality, and avoids the one dreaded feature of the old Mikulicz operation, viz., the high incidence of transplantation of tumor cells into the abdominal wound.

An acute obstruction due to a malignant tumor of the left half of the colon is a rather infrequent condition. When it is present no exploration or removal of the tumor should be attempted. The abnormal, distended gut does not lend itself favorably to anastomosis, with a secure suture line. Only the simplest of procedures in the form of a cecostomy or ileostomy should be adopted. When the fistula is functioning well, an exploratory laparotomy should be done, and the decision made at that time as to what type of operation is best suited for the case. In general, resection of the tumor and an end to end anastomosis is indicated, because there still exists a safety valve in the form of the preliminary cecostomy or ileostomy. This decompression measure has also permitted the inflammatory reaction around the tumor mass to subside, and hence resection is made easier.

In particularly favorable cases, where the condition of the patient is good, with little or no obstruction, dehydration or loss of weight, it seems wise to resect the tumor and do a primary anastomosis. A cecostomy or ileostomy should be established as a safety valve in those cases where there is any doubt about the firmness of the suture line.

If the patient is obese, or there is considerable inflammatory reaction about the tumor, which makes it difficult to adequately mobilize the segment of gut, a primary resection and anastomosis is also indicated.

On the other hand, the majority of patients with malignant tumors of the left half of the colon present signs of chronic obstruction, in which thorough cleansing of the colon is often difficult. Experience indicates that the so-called "obstructive resection" or modified Mikulicz operation is a safer procedure, and is attended by a lower mortality than the primary resection and anastomosis, even though somewhat greater hospitalization is required in this multiple stage procedure. However, in considering the factors that determine the selection of an

operation for a given case, the economic factor is a decidedly secondary one as compared to the life of the patient.

Operative Procedure

An incision is made over the tumor mass. The lateral peritoneal reflection is incised to permit adequate mobilization of the tumor-bearing segment toward the median line. Care must be exercised to prevent injury to the left ureter, which tends to be lifted up with the peritoneum. The vessels supplying the segment to be resected are then visualized and ligated near their origin at the root of the mesentery. The ligation of these vessels frees a triangle of mesentery to be resected with the tumor. (See Fig. 1.)

The three-blade Rankin clamp is applied so as to include a segment of intestine at least two or three inches on either side of the tumor, with the handle of the clamp extending across the abdomen to the right. A similar straight clamp is applied distal to the Rankin clamp, between which the tumor bearing segment of intestine will be cut away with the electric cautery. (See Fig. 2.)

The mesenteric edges of the two limbs are sutured together, the peritoneal edges over the lumbar gutter are approximated to eliminate raw surface, and the limbs of the colostomy are apposed, if possible, with interrupted sutures. (See Fig. 3.) It is preferable to bring the teniae coli in apposition, where practicable, in preparation for the application of a straight clamp to the spur. This eliminates the possibility of hemorrhage when the clamp is applied to the spur in the region of the longitudinal bands rather than through the mesenteric region, with subsequent release of a mesenteric vessel.

After this preparation of the limbs of the colostomy, the tumor and adjacent intestine and the metastatic area of the mesentery are cut away with the cautery. (See Fig. 3.)

The incision is closed snugly around the two limbs of the colostomy. No sutures are placed between the peritoneum and the intestine, for adherence between these surfaces is firm in 48 to 60 hours. (See Fig. 4A.)

The proximal blade of the clamp is released on the second or third day, or earlier if distention demands. The distal

blade necroses through and comes away spontaneously in about seven days. A double-barrel colostomy then results. (See Fig. 4B)

After this clamp comes away, the septum is cut down by applying a long blade, straight clamp to the septum. (See Fig 5A.) It is lightly locked when first applied, and gradually tightened every day or two, or constant pressure is applied by looping a strong rubber band around the handles of the clamp. Usually it is necessary to reapply the clamp in order to cut away sufficient of the septum to form an adequate new lumen.

After the septum has been removed, the patient is sent home for 3 to 6 weeks to

Fig 4 A Wound is being closed around the double-barrel colostomy, without sutures between the abdominal and intestinal walls B Double-barrel colostomy after removal of the Rankin clamp.

Fig 5 A Application of the straight clamp to cut away the septum between the afferent and efferent loops of the colostomy B Extraperitoneal closure of the colostomy

Fig 6 Colostomy has been closed extraperitoneally in a direction transverse to the longitudinal axis of the intestine

allow him to regain his strength, and to cause the granulations at the mucocutaneous margin around the colostomy to completely heal before the extraperitoneal closure of the colostomy is done.

Closure of the colostomy: After thorough cleansing of the proximal and distal portions of the colon, the operation is done preferably under spinal anesthesia. An incision is made around the colostomy about one-quarter inch lateral to the mucocutaneous margin. This skin margin is closed temporarily over iodoform gauze. The incision is then deepened and the layers of the abdominal wall are freed from the limbs of the colostomy down to the peritoneum. The wound is packed with iodoform gauze and entirely protected from the colostomy opening. The encircling rim of skin is excised.

The mucosal edge is then approximated and inverted with continuous catgut suture, in a direction transverse to the intestinal axis, so as to reduce the narrowing to a minimum. A second line of suture then inverts the mucosal suture. (See Fig. 5B.) The closed intestine is gently pressed into the abdomen, without disturbing the continuity of the peritoneum. (See Fig. 6.) The fascial and muscular layers of the abdominal wall are

closed en masse with interrupted mattress sutures.

The fat layer and skin should be left open, and this part of the wound packed lightly with iodoform gauze over silk or rubber tissue. The fat is more easily infected, and the closure of this layer with subsequent infection may mean failure of the hernial repair. The packing is removed on the fourth or fifth day, when the edges of the wound are pulled together with adhesive. This most often results in primary union.

Conclusions

(1) The modified Mikulicz operation includes the resection of the tumor and adjacent intestine, together with the corresponding metastatic area of the mesentery.

(2) It is a safer procedure, it is technically easier of execution, and, therefore, has a wider field of application than the primary resection and anastomosis.

(3) It eliminates, in so far as possible, the implantation of carcinoma cells into the abdominal wound.

(4) It permits as radical resection of a given tumor as can be accomplished by any other procedure.

121 EAST 60TH STREET

NEW DIRECTOR OF INDUSTRIAL HYGIENE

State Industrial Commissioner Elmer F. Andrews has announced the appointment of Dr. Leonard Greenburg of New York, former health officer of New Haven, Conn., as executive director of the Division of Industrial Hygiene, State Department of Labor. "Dr. Greenburg is internationally recognized as an authority on industrial hygiene," Commissioner Andrews said. He has contributed widely to scientific periodicals on occupational diseases, industrial sanitation and ventilation, dust content of air and its effects on the health of the

worker, lead in the atmosphere, lead and benzol poisoning and kindred subjects.

Dr. Greenburg has served as chairman of the Chemical Section, of the Industrial Health Section and of the Occupational Disease Committee of the National Safety Council; and many other similar positions. He was graduated at Yale University in 1923 with a Ph.D. in public health and at the Yale University Medical School with a degree of M.D. in 1930. He received his license to practice medicine in New York State in 1930.

AN ABUSE TO BE HALTED

It has been discovered that medical sphygmomanometers, manufactured for physicians' use only, are being used by persons outside the profession. Manufacturers are unable to trace the leak, and are asking the aid of the profession. The President of the Taylor Instrument Companies, of Rochester, says in a letter:

"We deplore deeply any such mis-use of instruments designed and produced solely for the medical profession. We are greatly

disturbed when the Certified Tyco becomes a plaything in the hands of people who employ it unethically and ignorantly for commercial gain in amusement parks. If any of our friends discover how these instruments are procured for any unethical purpose, we shall appreciate knowing about it. Such information will, of course, be considered confidential, but will aid us in taking any steps possible to prevent continuance of the practice."

THE PROGNOSIS OF CANCER OF THE CERVIX TREATED BY IRRADIATION

MITSON B. SACKETT, M.D., F.A.C.S., *New York City*

In evaluating a method of treatment for malignant disease, our first consideration should be salvage or prolongation of life, but conservation of health and happiness is nearly as important, perhaps more important from the standpoint of the survivors and their relatives. The following report will touch on the five-year and ten year salvage of life by radiation therapy for carcinoma of the cervix, and be devoted chiefly to a study of the health of the survivors as indicated by the complications observed and treated in the Cancer Clinic of the Woman's Hospital, directed by Dr. G. G. Ward.

Table I indicates that one in four unselected cases,¹ one in two cases with cancer clinically limited to the cervix, and seven out of ten very early cases will survive at least five years after primary radium treatment.

Table II shows that about one in six unselected cases, two out of five clinically localized cases, and two out of three very early cases will survive ten years or more. We have shown elsewhere² that about 70 per cent of the patients surviving five years have lived ten years or longer in spite of the lowered life expectancy in their respective age groups. But we know of several patients symptom free for ten or more years, in whom cancer of the uterus as the cause of death was proved or not definitely excluded.

Although our experience with adjuvant roentgen therapy cannot be evaluated until after 1937, the vast improvement in results thus obtained by Regaud³ leads us to hope that the accompanying tables do not express the optimum attainable.

Cancer propaganda has apparently not yet improved the material handled at the Woman's Hospital. In Table III it is noted that cancers clinically limited to the cervix comprise 21.6 per cent of all cases seen in the eight years 1919 to 1927 while they total only 18.4 per cent of all

cases seen in the seven years 1928 to 1934.

Careful pathological studies⁴ have failed to give a dependable prognostic significance to the histological type of the cancer, the size of its cell clusters,⁵ or the stromal and leukocytic reaction. Until an index of radio curability is forthcoming, we must treat all histologic types alike, and watch each patient every month in order that those which prove radio resistant (40 per cent according⁶ to Regaud) may be identified in time for appropriate radical or palliative surgical measures.

The incidence of cancer in the stump following supravaginal hysterectomy is shown in Table IV to be over seven per cent. Inasmuch as the dangers of treatment are the same, all stump cases are included regardless of the lapse of time between the hysterectomy and the first irradiation. This time interval was three years or less in twenty-four cases, four or more years in twenty-three cases.

The total salvage including adjuvant roentgen therapy will not greatly surpass thirty cases per hundred, or with universal early detection and treatment, double that number. Further reduction in the uterine cancer toll will depend on more widespread adoption of prophylactic measures. Conservative obstetric, immediate or intermediate repair or cervical lacera tions,⁷ appropriate correction of puer peral⁸ and infectious erosions and endocervicitis,⁹ total instead of supravaginal hysterectomy¹⁰ for benign conditions were technically feasible—these measures will forestall thousands of cervical cancers. This gain, however, must be balanced against the dangers inherent in each procedure, some of which—stenosis, cavitation, and malignant degeneration—have been recently emphasized by Curtis¹¹ and by Bullard.¹²

The health of patients surviving primary treatment for cancer of the cervix

is roughly indicated by the incidence of complications summarized in Table V. Since about three-quarter of all cases die within five years, it is fair to assume that the figures are weighted by the disease itself. This inference is borne out by Table VI giving the complications in patients surviving treatment over five years and over ten years. Hemorrhage, intestinal obstruction, and disorders of the rectum, bladder and urethra, upper urinary tract, and nervous system are strikingly less frequent in the survivors as compared to the entire series. On the other hand the slight increase in number of fistulae and gastric upsets, and the great increase in blood-lymphatic obstruction in the survivors point to the irradiation effect. Circulatory obstruction was noted in 9.5 per cent of the forty-two ten-year survivors, compared to 3.1 per cent of all cases seen. Only parallel tables based on untreated and surgically treated patients can differentiate the disease effect from the irradiation effect.

Complications, whether caused by irradiation, by the progress of the cancer itself or by both, can be discussed accord-

ing to the system affected. In the internal genitalia we observed both acute and chronic inflammation: pyometra in fifty-five cases, occasionally present before treatment; severe hemorrhage in eighty-nine cases; and one case of bilateral hydrosalpinx in association with frozen pelvis.

In the blood and lymphatic system we observed phlebitis in five cases, and obstructive lymphedema affecting the suprapubic, vulvar, inguinal regions, thighs and legs in twenty-three cases. The disorder was bilateral in half the cases; and in most instances the signs progressed hand in hand with the spread of carcinoma to a fatal termination. But in the four cases where the signs subsided under treatment it is reasonable to suppose that the obstruction was due to inflammatory and productive changes initiated by the irradiation.

Symptoms referable to the upper alimentary tract occurred in fourteen cases, eight of which had nausea and vomiting and another was treated for "gastric ulcer." Independent malignancy of the stomach or pylorus was the cause of

Untraced, counted dead from cancer 12 (4.9 per cent)

death in three cases, respectively, eleven, ten, and seven and one half years post radiation in four others inoperable carcinosis of the uterus and ovaries, rectum, intestines, and peritoneum was demonstrated. Only 6 cases have survived long enough to indicate that the gastric symptoms were purely due to radium or x-ray.

Intestinal obstruction occurred in twenty five cases, and was the cause of death in nine, of which five were operated upon with three postoperative deaths from peritonitis, and four died without operation. Spreading carcinoma was proved in nine out of eleven cases coming to laparotomy or autopsy. Nevertheless seven cases were more or less relieved by operation, two are still alive at three years and two and one half years after operation, and we agree with T. E. Jones¹³ of Cleveland that exploratory laparotomy is justified for exact diagnosis, cure of benign strictures, and relief of starvation and cachexia in obstruction due to malignancy.

Of the forty-two rectal disorders noted in the entire 688 cases, proctitis or its symptom triad of tenesmus, bleeding, and diarrhea occurred in thirty-five patients, fifteen of whom died within four months after rectal symptoms were noted. In most of the others the rectal symptoms subsided and five of the group are among the five-year survivors. Carcinomatous invasion of the rectum was demonstrated in three cases, stenosis four times, benign ulceration several times, and angulation from extrinsic mass twice.

Sixty patients, or 8.7 per cent of the total seen, developed seventy-three fistulae divided as follows:

Rectovaginal 25, with 1 operative closure
Vestibulovaginal 22, with 1 operative closure
Rectovaginal and vesicovaginal 8, with 4 spontaneous closures of the rectovaginal fistula and one spontaneous closure of the vesicovaginal fistula
Rectovaginal and intestinovaginal 2
Rectovaginal, ureterovaginal and abdominal fecal 1
Rectocervical 1
Vesicovaginal and abdominal fecal 1

The incidence of fistula in untreated hopeless cases was 22.2 per cent, it occurred in six (12 per cent) of the fifty hysterectomy stump cases. Reradiation was implicated in one half of the fistula cases. The disease was spread beyond the cervix in eighty-five per cent of the cases subsequently developing fistula.

Twenty-six women developed symptoms referable to the nervous system; one suicide occurred in a patient with metastases in the lungs, another with signs of brain metastasis had a severe psychosis and the others suffered pain in the lower abdomen, groins, pelvis, sacroileum, and sciatic regions. The low incidence of these symptoms in the five- and ten-year survivors indicates their grave prognostic significance. Sympathectomy and cordotomy are in our opinion still *sub judice*.

In the lower urinary tract we observed a total of sixty-seven disorders in 688 cases, or 9.8 per cent. Excluding those in the first year after irradiation there remain thirty-seven cases of which eleven revealed extensive cancerous involvement of the pelvis, bladder, or urethra. The other twenty-six cases (3.8 per cent) comprise five strictures of the urethra,

TABLE III
Extent of Disease, by Schmitz Classification in Two Groups of Patients with Carcinoma of Cervix Uteri at Woman's Hospital

		I	II	III	IV	V	Total
8 Years 1919-1927	Number	4	73	249	31	0	357
	Per cent	1.1	20.5	69.7	8.7	0	100.0
		Early cases 21.6 Per Cent		Late cases 78.4 per cent

	Per cent	4.0	14.4	72.5	7.7	1.3	100.0
		Early cases 18.4 per cent		Late cases 81.5 per cent			

six cases with ulcer or slough in the bladder, and fifteen cases diagnosed as cystitis or trigonitis by the cystoscope or because of the symptom triad of frequency, dysuria, and hematuria. Since ten of the twenty-six cases survived irradiation less than three years it is fair to conclude that the cancer itself was at least partly responsible in two-thirds (21 out of 37) of the patients suffering late bladder disorders. From the Memorial Hospital, Dean¹⁴ reported 2.1 per cent of late or "tertiary" bladder reactions (urethra not included) after irradiation for primary carcinoma of the cervix.

Upper urinary tract disease occurred in thirty-nine or 5.6 per cent of 688 cases, and with about the same frequency in those patients who survived five years and ten years. Pyelitis, renal abscesses, or pyelonephritis on one or both sides occurred in fourteen instances including four present on admission and one case too far advanced for treatment. Unilateral pyonephrosis occurred six times, four nephrectomies including one for tuberculosis being done; and bilateral pyonephrosis was demonstrated three times. Hydronephrosis was noted nine times, being present once on admission, twice with associated hydroureter, twice with active carcinoma demonstrated in the parametrium or iliac fossa. In five other cases of obstructed ureter parametrial cancer was demonstrated, while in two excised specimens carcinoma cells were seen in the wall of the ureter itself. Ureterovaginal fistula occurred once, chronic nephritis four times, and uremia

seven times. Bugbee¹⁵ has reported six of the above cases of ureteral occlusion in greater detail.

We believe urinary tract obstruction may frequently be demonstrated by routine cystoscopic studies long before symptoms supervene, that it is the cause of much of the suffering of irradiated cancer patients, and that it can often be relieved. Prompt detection of the side first involved offers the best hope of a successful sidetracking operation while renal function on the other side is still adequate.

Summary and Conclusions

(1) Treatment of carcinoma of the cervix by radium and roentgen rays prolongs life from five years in one-fourth to one-third of all cases, and for ten years in one-sixth to one-fifth of all cases.

(2) This salvage could be doubled if the cancer was detected and treated when still limited to the cervix; but cancer propaganda has apparently thus far failed to increase the proportion of early cases.

(3) Further reduction of the cancer toll, therefore, depends on more widespread use of prophylactic measures, with due regard to the dangers inherent in these procedures.

(4) A study of the complications observed in 688 cases, and in five- and ten-year survivors indicates (a) that except for hemorrhage each complication occurs in less than ten per cent of patients; (b) that most complications are *less* frequent in patients destined to survive than in the entire series, and that many complications in the survivors are transient or

TABLE IV

*Incidence and Curability by Irradiation of Carcinoma of Cervix Following Supravaginal Hysterectomy**

Schmitz Class	I	II	III	IV	V	All Classes	Early	Late
Total seen.....	4	9	31	5	1	50	26%	74%
All treated.....	(8%)	(18%)	(62%)	(10%)	(2%)	(100%)		

Incidence: 50 in 688 Cases seen, or 7.3 per cent

Incidence: 50 in 664 cases treated, or 7.5 per cent

Series	Total Seen	Irradiated	Living 5 Years	Living 10 Years	Survival Rate Abs. and Rel.
1919, to May 15, 1930.....	31	31	15	..	48.4% At 5 Yrs.
1919, to May 15, 1925.....	16	16	7	4	25.0% At 10 Yrs.

* Without regard to time elapsing between hysterectomy and first irradiation. This interval varied from two weeks to 18 years; it was 3 years or less in 24 cases, 4 years or more in 23 cases.

easily cured, (c) that complications are more frequent in untreated hopeless cases than in the entire series, (d) that complications often appear within a few weeks or months of death from the cervical cancer or metastases

(5) The above findings indicate that most complications are caused by the disease itself, and that their appearance is of unfavorable prognostic import. On the other hand the increase in blood-lymphatic obstruction in the five- and ten-year survivors points more to the irradiation effect

(6) Carcinoma of the stump following supravaginal hysterectomy occurred in over seven per cent of our cases, and the incidence of fistula in these patients was twelve per cent, or one and one half times the general fistula incidence

(7) Early detection and proper treatment of complications, especially obstructive lesions of the urinary and gastrointestinal systems will not only reduce suffering but prevent needless deaths and increase the five- and ten-year salvage by irradiation therapy for carcinoma of the cervix uteri

MENTAL TESTS OF AUTOMOBILE DRIVERS

In view of the tragic rise in automobile fatalities, medical and psychiatric tests of applicants for driving licenses and mandatory physical and psychiatric tests of licensed drivers at periodic intervals were advocated by Dr. David Kaliski, chairman of the coordination committee, Medical Societies of the Metropolitan Counties, at the Eastern Conference of Motor Vehicle

Administrators in New York.

He advocated the testing of drivers every five years up to the age of 55 or 60 and every year thereafter.

Dr. Irving Straus, connected with the New York State Bureau of Motor Vehicles, while questioning the practicability of universal physical and mental tests of drivers, endorsed Dr. Kaliski's position.

THE UNIVERSAL REMEDY

Had you been a European in the latter part of the sixteenth century your physician or herbalist would have prescribed a strange medicine for your minor illnesses as well as for your serious diseases. Corns or tetanus, cough or consumption, halitosis or cancer—it mattered not what the malady was—the remedy was the same.

This panacea, this perfect cure-all, was tobacco, which, from about 1560 to the middle of the nineteenth century, had an important place in the materia medica. A list of 100 maladies for which tobacco was used has been compiled from the books of the

period. These volumes are part of the library of George Arents, Jr. A fuller account of the ailments cured by tobacco, the *modus operandi* of nicotian therapeutics, etc., will be incorporated in the descriptive catalogue of the Arents library, which is about to be published in four folio volumes by the Rosenbach Company of Philadelphia and New York.

All the old writers were enthusiastic, of course, over tobacco's remedial virtues, insisting that the "divine herb" never failed in operation.

CIGARETTE SMOKE AS A HEALTH HAZARD

HERMAN SHARLIT, M.D., *New York City*

It has been said frequently, and with some justification, that the medical profession broke faith with the public in failing to inveigh vigorously against smoking as a menace to health. But it can never be held against our profession that it permitted itself, even by implication, to be involved in the endorsement of a tobacco product.

The cigarette industry is not a commodity business; by this I mean that the individual manufacturer makes no honest, wholehearted effort to claim a commodity better than his competitors. Each makes a cigarette that he feels will satisfy the public taste; he proceeds to exploit it by a type of advertising that concerns itself not at all with the inherent qualities of the commodity. In its truest sense the manufacturer's real commodity must never be discussed; it is taboo. A little reflection reveals the real commodity to be smoke—the dry, destructive distillation of wood (leaves); and what this smoke contains must be sung *sotto voce*. And so, carbon monoxide, ammonia, prussic acid, acetic acid, aldehydes including acrolein, the alkaloid nicotine and pyrrol, pyridine and other heterocyclic nitrogenous bases (generally grouped under the term "tars"), all products of the distillation and contained in the smoke, had best be forgotten for the greater happiness, perhaps, of the consuming public.

The manufacturer who sets out to make a more healthful cigarette must be prepared, however, to face these facts and to square his claims with them, at least when making these claims directly to our profession. The smoker knows, from practical experience, that old cigarettes produce a less agreeable smoke than fresh ones. The difference between the stale and fresh cigarette is simply one of water content of the tobacco. The cigarette stales by giving up original water content. To help maintain this original water content against the inevitable drying out, the manufacturer incorporates a hygroscopic agent in the tobacco mixture. The

agent generally used is glycerine. Since the late Thomas Edison lent his name to the assertion that the most harmful product of cigarette combustion was acrolein, glycerine as one probable source of this compound became widely objectionable. But decades of smoking glycerinated tobacco has proven the human organism fairly tolerant to the mixture containing it. Recently a manufacturer has substituted diethylene glycol for glycerine as a hygroscopic agent. The maker of a tobacco mixture containing a new combustible is at once on the defensive, at least from the point of view of public health, in that he has yet to know—if ever—that the new mixture is no more harmful than the old and tried mixture. And it is to the credit of that manufacturer that he set about to establish^{1,2} the harmlessness of this innovation. With the aid of the scientific ingenuity of a medical school laboratory, the demonstration was offered that not only did the new hygroscopic agent in the tobacco mixture produce a smoke less irritating than a similar mixture containing glycerine, but even less irritating than one containing no hygroscopic agent at all. This was all "proven" by judging the degree of edema of the conjunctivae of rabbits resulting from instilling into the eyes of these rabbits a water extract of the smoke from these different tobacco mixtures.

Without going into the character of the laboratory procedures for securing comparable smoke mixtures, these tests in the last analysis, were based on the judgment of an observer as to the amount of conjunctival edema induced in each experiment. All this, when there is at hand to every smoker, without benefit of medical school or laboratory, a test, fairer and more delicate; fairer, because it does not limit the test to the water soluble ingredients of the smoke, and more delicate, because the olfactory nerve ends in the mucous membrane of the nose are far more efficient than the eye for detecting irritating smoke. Indeed, that is precisely part of the job of these nerve

ends. When cigarettes made with diethylene glycol were so tested by the writer and several others (smoke quickly drawn up through the posterior pharynx and exhaled through the nose), they were found, unfortunately, to be quite as irritating as other cigarettes. Strangely enough, this simple test is as scientific* as that published in behalf of the diethylene glycol cigarettes. We do not wish to stress the reliability of these judgments, but simply to call attention to the fact that where elaborate laboratory procedures merely eventuate in a judgment based on an elemental sensation, these findings may be adequately checked in simple ways.

It may fairly be asked if, in the nature of things and viewed from the vantage ground of strict business, cigarette manufacturers can offer anything better or more certain to effect improvement in quality than changes of the nature we have been discussing. The answer is decidedly in the affirmative.

The writer has been interested in tobacco smoke chemistry for about ten years, during which time consultations with many executives in the industry have afforded occasional opportunities to penetrate the veil of secrecy generally assumed before outsiders, particularly physicians. The following is presented as a physician's analysis of the cigarette industry, viewed as a public health problem.

The tobacco industry, like all others, concerns itself with making money. It is an industry centuries old, steeped in an art that defies the amateurish dabbings of intruders and hypnotized into a belief in the sacredness of the leaves that are cured and blended. This latter spirit it has successfully striven to instill in the consuming public, with the result that there has been achieved for the industry a false public psychology, from which the industry, unmolested, or if you will, unassisted, will never dare retreat. The belief that cigarettes contain only pure, unadulterated tobacco is almost universal among smokers, and while vaguely aware

of flavorings in tobacco mixtures, they are blissfully ignorant of the ungodly messes of which they are composed. Having once taken the position that smoke quality is merely a matter of the quality and purity of tobacco, there is no place for publicity on the adulterants used in making the cigarette as good and as acceptable as it is.

What cannot be achieved by the art is attempted by suggestion through the printed word. Tobacco smoke is a mucous membrane irritant, if nothing else; and even the most confirmed smoker realizes that on occasion. And so each cigarette maker, after the manner of his copy writer, cries "It's mild." In seeking mildness the industry is endeavoring to meet a universal demand; irritating smoke drives the smoker to try another brand, with little or no relief, however, and so the industry is prepared to make any change in manufacturing that will give the requisite mildness, provided: (1) It does not at the same time produce a flatness of taste and odor which robs smoking of its "kick;" (2) it does not rob the smoke of such tasteless ingredients as some tobaccoists hold responsible for maintaining and cultivating the smoking habit (nicotine?); † (3) and provided the added treatment is of such a nature as to permit of publicity in keeping with the consumer's psychology of "the purer the tobacco, the better the cigarette!" Above all else, it must supply this advertising copy which is the life blood of the business.

Without entering into the bases for his belief the writer is satisfied that a tobacco smoke less harmful physiologically yet acceptable to the average smoker's taste will not result from a change in the combustion mixture, either through a change in the curing or blending of the tobacco leaf or the introduction of some new combustible into the tobacco mixture. This is exactly the approach to the general problem of tobacco production through the decades that has brought the cigarette to its present state of excellence, or the lack of it. There remains a simpler yet perfect approach to a solution—filtration of the smoke.

* Says the *Popular Science Monthly* of March 1935, concerning the professional taster of soap mixtures: "Despite its apparent crudity, this test is said to show the amount of free alkalinity in the soap with high precision, revealing in a moment what would otherwise require three to four hours of laboratory work."

† This, however, is a mistaken notion; there is never a physiologic craving for tobacco.

Removal of combustion products from the smoke stream may be effected by purely physical methods, or by the operation of physicochemical principles (absorbents). The former is merely a matter of supplying condensation surface to the smoke before it reaches the mouth. This may be accomplished by the use of cigarette holders or hollow tipped cigarettes containing small cotton plugs, but their use practically limits the removal of deleterious substances to the smoke tars. However, the consumer has evinced little interest in the use of any contrivance that produces a more physiologically tolerable smoke if by so doing it adds an atmosphere of artificiality to a habit which has become second nature. This has confirmed the tobaccoist in his conviction that a smoker does not smoke for his health, and that unnecessary fuss detracts from his enjoyment of a "good smoke."

Patent grants relative to the tobacco industry liberally cover the matter of adding absorbent materials to tobacco mixtures. In the main these materials are clays or claylike substances. It would lead us too far astray to enter into the reasons why most of these offered additions to the art cannot practically serve the purposes for which they are offered. But they all represent a proper approach from the medical standpoint in the effort toward producing a less harmful smoke.

It is apparent that filtered smoke can only be insidiously thrust upon the public. This requires the filter to be dispersed through the tobacco by way of one of these physicochemical absorbents. The writer has spent much time in the study of tobacco smoke absorbents and feels certain that there is at least one substance available for addition to tobacco that meets all the requirements. It is non-combustible and therefore takes no part

in the formation of the combustion products. It effects recognizable changes in the smoke when added to tobacco, to an extent of less than 1 part in 500, in even this small concentration it reduces the tar and acid content of the smoke, effecting mildness without flatness. Since the amount of filtration is a function of the concentration of the filtering material in the tobacco mixture, such a treatment of tobacco permits of effects upon smoke ranging from imperceptible influences on its original chemistry to one so thorough as to leave the smoke completely tasteless.

The medical profession, if it is to concern itself in the matter at all, should take the following position regarding cigarettes. Tobacco smoke cannot be considered harmless. The manufacturers of tobacco products are to be encouraged in their efforts to modify the art in behalf of a more harmless smoke, but, however good the achievement, the introduction of a filtering material into the smoke stream will effect a still safer smoke. The profession should assist in the production of a consumers' psychology sympathetic to the introduction of filters into cigarettes.

The physicians of the United States never have endorsed a tobacco product and probably never will, but they should be prepared to endorse and encourage the use of principles in the practice of the art where it is evident that such practices lead to the production of a less harmful smoke.

QUICK WORK

Remarkably quick action followed the editorial in the November 1 issue of the *STATE JOURNAL* on the proposed "survey" of deaf pre-school children in Monroe County. The project was to spend \$10,440 of public funds by the WPA on this survey, when there were only 14 such chil-

dren in the county. The State and County Medical Societies, the County Health Officers' Association, the District Health Officer and the other groups raised objections, and finally the *STATE JOURNAL* criticism appeared on October 31. The order was cancelled the next day.

EDITORIALS

Real Health Work

The unnecessary and inexcusable delay in starting PWA slum clearance projects is typical of the inconsistent attitude of bureaucracies toward health. Light airy homes would accomplish more for the poor in the way of mental as well as physical health than the most comprehensive program of sickness insurance. Yet many of the social reformers active in the Administration ignore the concrete benefits to be derived from proper housing and clamor instead for compulsory health insurance.

In New York City alone it has been estimated that 450,000 families are living in dark, airless tenements that are breeding spots for disease and corruption. Similar conditions exist, on a smaller scale, in every city in the state. Remedial projects have been hanging fire for several years—but the emphasis at Washington is still on social insurance rather than housing!

The situation has another aspect that is not wholly devoid of significance. Thousands could be put to work on housing projects but for the most part they would be poor laborers unsuitable to the formation of a strong political machine. The vast permanent bureaucracies of social insurance, on the other hand, are highly susceptible to political domination

and contain many lucrative sinecures for the supporters of those in power.

In commenting on the "inexcusable confusion and delay" in getting more PWA housing projects going, the *New York World Telegram* made the following pertinent criticism. "Organization and direction have gone badly askew amidst executive changes, bickerings and petty attitude of politicians notoriously oblivious of the fourth of the nation's population living and bringing up children in hovels." It would be regrettable in the extreme if the adoption of compulsory health insurance were to put medical care in the hands of those same politicians.

Penalize Violations

Under the amended Compensation Act, workers requiring further care after hospitalization should be referred to private practitioners on the approved panel. In spite of this provision, some hospitals continue to handle industrial cases after they become ambulatory. The violation is a profitable one to them for the fees collected from this work help materially to supply their treasuries. Their gain is medicine's loss.

The income from professional service to compensation patients legitimately belongs to the doctor and not to the hospital. The worker should go back to his

own physician wherever possible and as soon as possible. There is no reason to prolong emergency relations with the hospital once the emergency has passed and the patient is able to return to his home.

Since the profession has no effective means of compelling institutional regard for the intent of the new laws, it is up to the state to see that violations cease. If persuasion has no effects, penalties will become necessary for the success of workmen's compensation in this state depends on strict compliance with spirit and letter of the statutes enacted last winter.

It has been suggested that hospitals which persist in the treatment of ambulatory industrial cases be deprived of their tax exemptions. This is a fair proposal for the paid treatment of compensation cases is not part of the purpose or rights of tax exempt hospitals. Institutions which enter into competition with private practice and divert legitimate income therefrom should be required to contribute to tax funds in the same measure as the private practitioner must.

Group Malpractice Insurance

Pursuant to resolutions adopted at the October meeting of the Executive Committee there appears elsewhere in our columns a chronological sketch of events which led to the change in carrier from that of the Aetna to the new policy carrier, The Yorkshire Indemnity Company.

In our last issue we called attention to the financial responsibility of the new company and endeavored to clear any misunderstandings regarding this.

Today we urge all carefully to read the prepared statement which is official and authoritative. In addition, we wish to call attention to the fact that while the Aetna scrupulously carried out every obligation it undertook, the company is not to be credited with more than that to which it is entitled.

The fine record made under the group plan is not entirely due to the Aetna. Every phase of the controlling operations and the defense mechanisms has been

handled by our Society and not by the Aetna. The Society functioned through its representatives, its insurance committee, its officers, and its defense counsel.

From the Society's standpoint all that is needed from any carrier of the group plan is that the company handle the money, comply with the laws of the State of New York, and be financially responsible.

The members of the Society need no middle man. There is no need of insurance agents to act for our members. Our insurance committee acts for them, and as in the past, in the last analysis, it and the executive committee have the final determination in all moot questions.

With the retention of our able counsel, Mr. Lorenz J. Brosnan, and our insurance representative, Mr. Harry F. Wamvig, and with exactly the same insurance committee set up that functioned so well in the past, and with the financial status of the Yorkshire Indemnity Company fully established as qualified, there should be no concern felt by our members that the future will not be as successful as the past has been.

Finally, there may result from the newer arrangement financial returns of benefit to the Society and its insured members.

The Next State Meeting

Plans which are in the making for the ensuing meeting of the State Society which will be held in New York City, April 27-28-29, are rapidly maturing, and everything points to the promise of an exceedingly interesting meeting from the medical and scientific standpoints.

The Waldorf-Astoria Hotel which will house all the activities has made rates so that its facilities will be within the reach of everybody.

The scientific sessions, the scientific exhibit, and the public meetings are being developed in such a way as to present a rounded scientific résumé, inter-related with clinical material available on the topics in the university clinics and teach-

ing hospitals, and the exhibit will show details. The local committee in New York is arranging for a clinical day along such lines.

It is not too early for members desiring to participate in the scientific program to make their contact with their section chairman, and with the chairman of the scientific exhibits as space is limited, on both programs and in the hall where the exhibit will appear. We shall from time to time make note of the details of the program as its progress toward completion becomes available.

Estrogens and Mammary Carcinoma

It has been known for a long time that the function and structure of the mammae are regulated by hormones formed in other organs of the body. The role played by the ovary in increasing the size of the breasts at puberty and that of the placenta in enlarging the mammae during pregnancy were called to the attention of the profession by Halban thirty years ago.¹ Lathrop and Loeb,² Murray³ and others were among the earlier investigators who confirmed Halban's observations by experimentally producing mammary changes with the utilization of ovarian and placental extracts. The advance of biological chemistry, however, has resulted in the isolation and identification of the active principles responsible for the phenomena which had been observed. Collectively these are termed estrogens, the most important of which is estrin.

It seems that the normal function of estrin is the preparation of the breasts so that their anatomical structure will be suited for the physiological process of lactation which, in turn, is brought about

by the action of other hormones. This ability to produce a structural change in the mammae during pregnancy led Burrows⁴ to investigate the effect of prolonged administration of estrin on the mammae of non-pregnant female mice and of male mice. In all the experimental animals who were treated with estrin for a period of at least fifty days, a distinct proliferation of the ducts was seen. The mammary ducts in addition showed a dilatation which was definitely cystic in character. With continued injections of estrin, a definite hyperplasia of the epithelial lining was noted.

The observations of Burrows are worthy of studied consideration because of the generally accepted view that chronic cystic mastopathy is a precursor of mammary carcinoma. Differences of opinion do exist as to the role played by cystic mastopathy in the production of cancer of the breast but these can be attributed to the fact that they who agree as to its etiological importance base their view upon histological studies⁵ whereas those who discount its significance are guided more by clinical observation.⁶ The collective experience of workers in this field, however, emphasizes the close relationship between cystic mastopathy and cancer of the breast. Therefore, since the estrogenic substances are capable of producing cystic mastopathy and, furthermore, can bring about a hyperplasia of the epithelium lining the ducts, there would seem to be at least an indirect relationship between the activity and quantity of estrogens in the body and the appearance of mammary carcinoma.

This experimental work is provocative in that the knowledge gleaned from it may be utilized eventually for the pre-

vention of malignancy in this location. At the present time, the amount of estrogenic substances present in the blood and urine at different times can be estimated with a fair degree of accuracy. The reports of Burrows and others should stimulate the development of tests for the estimation of susceptibility to estrin so that the possibility for an individual woman to develop cystic mastopathy can be determined before it occurs. Should such tests be found, it then would be but a short step toward the isolation of antagonists for the treatment of an excess of estrogens in the body. Such a one is already known to exist in the form of progesterin, which is derived from the corpus luteum.

Prolongation of Life in Diabetes and Pernicious Anaemia

Since the advent of insulin in the treatment of diabetes and the use of liver to combat pernicious anaemia, there has been a great deal of discussion as to whether these remedies are accomplishing what has been expected of them. It is frequently forgotten that the sufferers from these ailments will be afflicted throughout life because their bodies have lost the power to manufacture a certain substance in sufficient quantity to cure the disease. A person has diabetes because the islands of Langerhans have ceased to function and he always will be a diabetic regardless of whether or not he exhibits any active manifestations of the disease. Hence, in estimating the value of the newer therapy for diabetes and pernicious anaemia, one must consider that it is employed not as a curative measure but for the purpose of keeping in abeyance the symptoms and destructive evidences of these maladies.

An analysis of the London Registrar-General's statistics of death by Scott¹ would tend to show that since the gen-

eralized use of the new methods for the treatment of pernicious anaemia and diabetes, there is apparent an average lengthening of the span of life for all persons with these diseases, amounting to three and one half years. Upon further analysis, diabetics under 55 years of age show a lengthening of life which amounts to about eight years. To further prove the efficacy of insulin therapy, an increase in the number of diabetics who die after their fifty fifth year has been noted since 1922 and is due, in all probability, to the postponement of death by the application of insulin therapy in the younger ages.

These statistics are all the more impressive when it is realized that they embrace all deaths from diabetes and pernicious anaemia without regard as to whether or not the newer means of therapy were employed. Nor has consideration been given to the adequacy of the treatment or to the continuance of the therapy by the patient. Despite these absent factors, insulin and liver therapy are shown, by Scott's study, to have been of inestimable benefit in the prolongation of the life of diabetics and those stricken with pernicious anaemia. Further gains are to be expected when the patients themselves will adhere more rigidly to the guidance of their physicians.

CURRENT COMMENT

THE NEW YORK MEDICAL WEEK, November 2, 1935 says, "Few citizens realize that internes in municipal hospitals receive no payment whatsoever throughout their period of service. These physicians who have completed an arduous and costly training and upon whom virtually all the routine medical duties of the hospital devolve must continue to depend on their families for clothing and pocket money while they are serving the city in an essential capacity."

ACCORDING TO EDWARD F. KLFIN, *JAMA*, November 2 1935 "In England the average number of panel patients (in 1935) for the average physician was nine hundred and sixty. A maximum number of 25,000 insured persons is fixed and no physician single handed may ordinarily have

¹ Scott, P. The Lengthening of Life by Modern Therapy in Pernicious Anaemia and Diabetes. *Brit Med J* Vol 1 P 1013 May 18 1935

more." * * * After a careful analysis of the whole English system, a study of its earnings and deductions, citations of penalties, Klein concludes with, "We, in the United States simply plead for the continuation of sane, simple medical economics." * * * Obviously if any conclusion can be drawn * * * it is that panel medicine is medicine in a hurry, it is medicine by fear and threats, by bookkeeping, by penalties, by regulations and by starvation wages.

BERNARD SHAW SAID, "A hungry doctor is perhaps more dangerous than a wild beast."—*J.A.M.A.*, Volume 105, No. 18, page 1437.

"ALL STATES upon which a premium is set tends to become more common," says C. W. Armstrong, in "The Survival of the Unfittest." Edward F. Klein, *J.A.M.A.*, cited above, continues, "If sickness and unemployment receive as premium a free gift of other people's money, these states will therefore tend to spread. * * * As soon as material reward is to be gained with less effort in neglecting health, work and thrift, such negligence tends to increase. * * * The evidence is conclusive that, despite the payment of extraordinary sums, compulsory health insurance is an absolute failure to reduce the amount of sickness of workers."

THE THIRD FUNCTION OF THE GOVERNMENT.—Such efforts as slum clearance and public construction of houses must be kept clearly set off from private construction as an area of social experiment. They include only a tiny fraction of the general home building that should be undertaken. A volume of building sufficient to bring down cost, to provide widespread re-employment and to raise the standard of living of millions of people can only be provided by private enterprise, says Raymond Moley, in "*Today*," November 2, 1935.

IF ORGANIZED MEDICINE, with all the authority of its humanitarian and vested interest in the prevention of automobile casualties, does not insist upon and demand yearly physical examination by qualified physicians for drivers of motor vehicles, and present a comprehensive plan for them to be carried out, then organized medicine must also share the guilt for joint negligence which makes many of the horrible motor accidents possible. Thus says Dr. L. D. Redway, Chairman, Public Relations Committee of the Westchester County Medical Society.

"GETTING GLASSES FOR THE CHILDREN has become a racket and various agencies have been helping make this service easy to obtain. * * * We have proved to the needy that the American people are generous, charitable and willing to give a hand. Let us now prove to those who can help themselves, that Santa Claus has been held up and black-jacked to death." From an editorial in the *Mamaroneck Daily Times*, September 20, 1935.

RAYMOND MORLY, in the October 19th issue of *To-Day*, speaking of the Relief Snarl, says "As the end of another year approaches, the vexatious public relief problem still hangs on like a veritable old man of the sea. Hardly a single member or friend of the administration regards the present situation as anything but a political liability."

A Correction

TAYLOR INSTRUMENT COMPANIES
ROCHESTER, NEW YORK

October 25, 1935

New York State Journal of Medicine,
33 West 42nd Street,
New York City, N. Y.

Gentlemen:

We are very much concerned over the article in your issue of October 1, 1935 (Page 976)—"New Appliance to Combat Gangrene"—especially, in the limiting of Dr. Hermann's experience to only fourteen patients.

And, also, particularly as to the statement that the Strong Memorial Hospital in Rochester—at the time of the publishing of your article—had the only PAVAEX in use east of Cincinnati. While the facts are,—there has been one in the Rochester General Hospital since June and "east of Cincinnati" approximately One Hundred Units in use.

In your next issue, will you not correct the statements made in your October 1st issue, as it is not fair to the Rochester General Hospital, or to the many other hospitals in the east which have now had the PAVAEX in use for some months.

Yours Sincerely,
HERBERT J. WINN, President

Society Activities

Committee on Malpractice Defense and Indemnity Insurance

THE GROUP MALPRACTICE INSURANCE PLAN

On January 1st the State Society's malpractice insurance arrangement with the Aetna Life Insurance Company of Hartford will be replaced with a new one in the Yorkshire Indemnity Company of New York. That announcement has created a lively interest in the Group Plan and the benefits which will flow from the new arrangements and, therefore, the Executive Committee of the State Society has instructed the Insurance Committee to prepare a chronological story of the Group Plan from its beginning down to date.

Twenty-five or thirty years ago the problems of malpractice insurance and defense were relatively unimportant factors in the practice of medicine in the state. The number of suits filed against members of the Society was small even compared with the smaller membership list of those days. The cost of operating the Society's legal defense service was moderate and the facilities of the office of the legal counsel were adequate to handle, with a satisfactory degree of success, all of the suits and claims filed. In addition, there were several good insurance companies willing to sell malpractice insurance policies at rates between \$12 and \$15.

A change began to take place, however, at about the time the war broke out in Europe. Each year showed an increase in the number of suits and claims filed against members throughout the state and similar increases were reported from other parts of the country. The awards made by juries also rose sharply and the seriousness of the situation soon forced itself upon the attention of the entire profession. In this state, the astonishing increase in the number of suits filed and the cost of disposing of them was regarded simply as an abnormal run of chance that would flatten out when the unsettled conditions, following the war, returned to normal. But as time went on, the situation grew worse, instead of better, until it became apparent that what had once been considered as normal had to be discarded as out of date. The medical professions finally concluded that it faced malpractice hazards that increased at about the same rapid rate as the traffic hazards on crowded streets.

The officers of the Society watched these

changes closely, fully appreciating the nature of the danger that lay ahead. They foresaw that unless some strong and positive action were taken, to unite all available defense elements into a solid front, medical men would shortly become ready targets for every damage-chasing lawyer that could get to their patients. In the absence of dependable insurance of some kind, members would have nothing to stand between them and certain worry, with possible financial loss, except the malpractice defense service of the Society. Even that service might have to be modified unless the Society were able to shoulder the steady increasing expense that was required to operate it.

In the fall of 1920, a general survey of the whole situation was undertaken and Mr. Harry F. Wanvig, at that time the vice-president of a New York brokerage house, was asked to look into and report on what could be learned from the insurance companies. He talked with the officials of all the companies writing malpractice insurance in the State and, without exception, found them discouraged with the outlook and loath to experiment further with that type of insurance.

Nevertheless, the Society had concluded that malpractice indemnity and defense could be provided at reasonable costs in this State only by combining the machinery and funds of an insurance company with the cooperation and defense service of the State Society. It was apparent that if a plan of that kind could be made feasible, it was necessary that it be based upon a cost-plus idea, together with a comprehensive scheme for malpractice defense by the Society. After a number of conferences, a plan for such an arrangement was drafted, having as its object three fundamental requirements. They were:

First, to relieve the Society of some part of its malpractice defense cost so that it might continue that service for uninsured members without increasing its defense appropriation.

Second, to prevent, if possible, a heavy increase in the cost of malpractice insurance rates for individual members.

Third, to preserve for all members those excellent and highly necessary principles of defense that the Society through its legal counsel had so painstakingly established.

The cost-plus idea was conceived and the

detailed organization carried out by Mr. Wanvig. It is obvious that the organization and operation of a cooperative enterprise, such as the Group Plan, requires management by some one thoroughly familiar with the insurance problem and one whose viewpoint and experience are quite different from that acquired by insurance agents and insurance brokers. In working out the details of group insurance since its inception, it was necessary for your Society to have an insurance specialist who was familiar with every detail of malpractice insurance. He had to enjoy the confidence of the company on the one hand and the Society on the other and know exactly what the insurance company was entitled to, but in a larger measure what the members of the Society were entitled to, and how to keep the details of organization and operation constantly in order for the benefit of the Society.

The cost-plus idea is an example of the former and the present low expense ratio of the Group Plan is an adequate demonstration of the latter.

On behalf of the Society, Mr. Wanvig offered the plan to all the leading companies but each of them declined to consider it. Finally, after several months of persistent effort, the Aetna Life Insurance Company was persuaded to accept the Society's theory and to undertake the Plan.

Late in April, 1921, an arrangement embodying the three stipulated requirements, was concluded with the Aetna and ratified a few days later by the House of Delegates that met in Brooklyn that year. On May 1, 1921, the plan which came to be known as the Group Malpractice Insurance Plan of the Medical Society of the State of New York was put into operation, and Mr. Wanvig was appointed Insurance Representative of the Society to manage it.

In addition to covering many routine matters that had to be provided for, the arrangement with the Company was based upon three provisions that contained the heart of the undertaking.

1. *That all suits and claims against insured members would be handled exclusively by the legal counsel of the Society.*

This was a bold experiment, because so far as we know, it was the first time in the history of insurance that a company had been induced to turn over the defense of claims, for which it was liable, to the legal counsel of the policyholder. It was a very important provision so far as the members were concerned, as that was the only way in which highly specialized and competent legal defense could be guaranteed to them.

2. *That the Company would issue policies*

only to members in good standing of the State Society.

This was likewise an important provision because it eliminated the possibility of suits and claims against nonaffiliated doctors, having an unfavorable influence on the loss experience charged to the Society.

3. *That the Company would conduct the business for the Society on what amounted to a cost-plus basis.*

In the original negotiations with the various insurance companies, Mr. Wanvig had insisted on a base rate in the neighborhood of \$15, and in the agreement with the Aetna a tentative rate of \$18 was named. To protect the members in case that rate proved too high, and to protect the Company, and thus insure a continuing source of insurance for the members in case the rate was too low, it was agreed that the original rate of \$18 would remain fixed for a period of three years while the undertaking was being tested. At the end of that time it was to be increased or decreased so as to cover the actual cost of the business plus the stipulated handling charge or profit.

The arrangement further provided in detail the manner in which the cost would be computed, and fixed the amount which would be charged to the Society's experience for Expenses. Under such an arrangement there could be no question of unfairness to either the policyholder or the Company, and no opportunity for one to profit at the expense of another.

At the end of the first three-year period, Mr. Wanvig and Mr. Whiteside, who at that time was legal counsel for the Society, went to the home office of the Aetna in Hartford where the tabulated experience of the Group Plan was presented for their examination.

They found that although the Company's attitude had been sympathetic and their cost data carefully and scientifically tabulated, the cost of insurance per doctor per year for the minimum policy had been \$30.06, as against the rate of \$18 which members had been required to pay.

In accordance with the letter of the Society's arrangement with the Company, recognition of that cost was necessary in considering the rate adjustment due at that time. In analyzing the cost sheets, however, special attention had been drawn to the fact that the losses caused by x-ray therapists had been far in excess of those of the other branches of the profession. This was consistent with the Company's experience in other parts of the country and bore out the contention of the Fidelity and Casualty Company three years before, that the cost of x-ray therapy insurance in New York

was in the neighborhood of \$100. The Aetna would have been glad to discontinue insuring that specialty, but a compromise was reached whereby x-ray therapy was reclassified with a surcharge of \$75 and the base rate for the rest of the profession was raised to \$24.

Before the Group Plan was organized, the Fidelity and Casualty Company of New York wrote most of the malpractice insurance in the country. It had a longer experience with a greater volume of this business than any other company. The vice president in charge of its malpractice insurance business was a doctor and a member of the State Society, and its legal department attained considerable ability in handling malpractice claims. Regardless of this favorable position, the company found in 1921 that it required a rate of \$45 for its minimum policy excluding x-ray therapy. Even that rate did not prove to be high enough and a year or two later it discontinued its malpractice insurance department. Had the company remained in business, it would have been necessary to increase even that rate, as each year since that time has brought a steady increase in the number of suits filed and in the cost of disposing of them.

During these troubled years, the cost for similar insurance under the Group Plan has averaged only \$26.66, although over 3000 suits and claims have been closed with all liabilities fully discharged.

While this is a record in which insured members can find ample cause for confidence and a feeling of security, they should remember that this achievement would not have been possible except for the cooperation and supervision of the Plan by the State Society through its legal and insurance departments. Without that direction by the Society, no scheme for writing malpractice insurance in this State can succeed at rates less than nearly double those required by the Group Plan.

While everyone who has watched the defense of a malpractice suit in his community is familiar with the splendid work of the Society's legal department, only the members of the Insurance Committee come in contact with the work of the insurance department where the business is managed. In that department individual records are kept, tabulations checked, reserves tested, rates computed, plans made, controversies settled and needed changes initiated and worked out. And it is through this agency that the organized group power of the Society as a whole is brought to bear upon the malpractice insurance situation in the State. The work of this department would

never appeal to the interest of a busy doctor, but its labor protects his malpractice insurance welfare quite as much as does any other effort put forth on his behalf.

So far this discussion has dealt with the causes which brought the Group Plan into existence and the part which the Society played in its conception and organization. In addition, it has endeavored to present some idea of the extent to which the Plan is, in fact, a Society-controlled activity and the effect which that control has had upon the cost of malpractice insurance in this State. Some knowledge of these fundamental facts is necessary for a better understanding of the situation which has been created by the Society's decision to transfer the Group Plan from the Aetna to the Yorkshire Indemnity Company on January 1st.

A wide interest has been expressed in the Society's reason for terminating its agreement with the Aetna. The Company has proved itself to be a reliable institution. It has lived up to its arrangement with the Society and the Society has lived up to its arrangement with the Company. It has fully discharged all of its contract and moral obligations to the policy holders and for all of this the Company is entitled to the commendation it has received from the Society. However, to members who may be inclined to lay too much stress on the satisfactory manner in which their claims were handled, it is only fair to point out that those claims were defended and handled by the Society's legal counsel with all the power and prestige of the State Society behind him. Also, it should be remembered that any carrier of the Group Plan must meet its obligations fully and fairly because the money involved is furnished by the members, and, under the arrangement, the Society is in a position to see that liabilities are discharged in that manner. The carrier of the Group Plan has as little to do with its success than a bank has with the success of the corner grocery simply because the bank finances the grocery store. The success of the undertaking is due entirely to the group power of the State Society, skillfully applied by competent men in its legal and insurance departments. This fact cannot be converted and the sooner it is made clear to the members of the Society the better it will be for all concerned.

As pointed out above, the defense of claims is only a part of the Group Plan. The other part, composed of the business and rate making details, is equally important to the success of the Plan, and it was the Company's attitude towards some of those details which led to the Society's decision to make a change.

During the years since the Group Plan was organized many changes have taken place in the manner in which members carry on their practice requiring, in the opinion of the Society, changes in the forms and methods of handling the Group Plan so as to make the insurance protection more closely fit their needs. These changes include such items as the method of providing protection on account of the use of permanent assistants, making a new provision to cover the employment of temporary or emergency substitutes, revising the policy to agree with the rules of the Society, etc. Partly because the Aetna's forms were in general use throughout the country and for other reasons which it considered sufficient, the Company has been loath to make any extensive changes to meet the requirements in New York. Taken by themselves, none of these items was important enough to warrant seeking a new carrier for the Group Plan. However, they were given due weight when the matter of cost accounting and rate making brought the whole agreement into question.

In a cost-plus contract, it is essential to determine and agree beforehand the exact manner in which the cost shall be computed, covering among other things the amount which shall be added for operating expenses. Similar provisions were made in the original arrangement with the Aetna in 1921. At that time, it was agreed that the Group Plan would be charged with an expense loading substantially less than the published expense ratio of the Company. This favorable differential was possible for a number of reasons, all of which tended to reduce the cost of operating the Group Plan. From time to time other economies made it possible to further reduce this charge until, at the present time, the Plan is being operated with a lower overhead than that charged to any other stock insurance operations in the State.

In the meantime, the Company's general expense ratio had also been reduced so that at the end of 1934 the differential in favor of the Society was somewhat less than it was in 1921, although the Plan was being operated more economically than at any time in the past.

Disregarding this fact, the Company, this year asked the Society to approve an increase in this item to the 1928-30 level where the difference in favor of the Group Plan would have been negligible. Had the Society approved this proposal, an increase of about 3.5% would have been added to the expense loading in the premiums of every insured member of the Society.

In addition, a change in the general policy of the Aetna, with respect to its reserves for

outstanding losses, resulted in a substantial increase in the reserves charged to the loss experience of the Group Plan. This was not aimed specifically at our Group Plan; in fact, it is doubtful if the officials who directed the new policy even knew of the existence of this tiny bit of their enormous business. Nevertheless, it seriously effected the cost of the Group Plan to our members and was entirely unnecessary. Every year the cost of suits and claims against our members ran well below the reserves established for them, until the accumulated saving on this account had reached an impressive total. This indicated beyond argument, that no increase in our loss reserves was needed and, therefore, could not be approved by the Society.

Had both of these requests been approved, the base premium for a minimum policy would have risen to \$37, an increase of twenty per cent in the cost of malpractice protection in this State. And, what is even more important, all future rates would have been computed on that basis.

The Society, through Mr Wanvig, protested these proposed changes and a substantial reduction was made in the outstanding loss reserves, bringing the computed cost of Group insurance down to \$34. But, this still required an increase of over thirteen per cent in the current rates.

Your Society has never hesitated to grant increases in rates where it could be shown that they had been made necessary by increases in the amounts paid in settlement of claims or needed expenses. Had the proposed increases been predicated upon a proven necessity of that character, it seems likely that they would have been approved and recommended to the Executive Committee. However, since the proposed increase was based entirely upon a change in the method of cost accounting by the Company and not upon our own accrued loss experience, the Executive Committee were unable to convince themselves that the increase was either necessary or justified.

This bookkeeping increase which your Society was asked to approve, in addition to the fact that the Aetna was unable or unwilling to grant improvements in forms and methods of handling which the Society considered desirable, led inevitably to the conclusion that a change had taken place in the attitude of the Company. Possibly circumstances had led them into a new conservatism from which they were no longer able to take a helpful view of the situation in New York. At any rate, it was clear that a reaction had taken place and that the progressive and economical cooperation which the Society regards as vitally necessary to the existence of the Group Plan and

the service it performs could no longer be obtained under the old arrangement with the Aetna. When that conclusion was definitely, though reluctantly reached, there was no alternative to its termination.

The Yorkshire Indemnity Company was organized in 1926 under the laws of New York by the Yorkshire Insurance Company, Ltd., of England, which owns all of the capital stock. Its financial statement furnishes an interesting study to those who have watched developments in the insurance world during the past few years. Organized and owned by one of England's oldest and finest companies, it was endowed with a heritage of sturdy conservatism that stood it in good stead during the years of the depression when its safe investment program and sensible limitation of production kept it out of financial difficulties and retained for it the high rating of A+ given it by the Alfred M. Best Company of New York. No better indication could be found of the good judgment of the parent company than in the limited manner in which they started their Indemnity Company. This is emphasized by recalling that this took place at a time when other companies were giving more thought to the number of digits of capital they could use for advertising than to the problems of establishing sound and lasting institutions.

In the October 15th issue of this JOURNAL, a statement by the Insurance Committee was published regarding the Yorkshire Indemnity Company. That statement should serve to reassure everyone as to its stability so far as it concerns the Group Plan, but a further examination of its position is enlightening.

Solvency in an insurance company is not hard to define or understand. Its assets must be adequate, sound and liquid. It must establish and maintain ample reserves for various contingencies, the most important of which are its loss and unearned premium or re-insurance reserves. The latter is a fund from which unearned premiums can be returned to the policy holders or used to purchase re-insurance from another company to cover the liability which it has under its outstanding policies in case it encounters financial difficulties or decides to retire from business. Back of these reserves, as an additional protection to the policy holders, stands the company's capital and surplus. Assuming, as is usually done, that a company's loss reserve is always adequate, the test of a company is not the size of its surplus to policy holders but the ratio which that surplus bears to its unearned premium liability.

Turning to the Spectator Handy Chart for 1935, showing the financial position of all companies at the first of this year, an

interesting comparison can be made of the relative positions of the Yorkshire with the Aetna Life Insurance Company and the Aetna Casualty and Surety Company, to which the Group Plan would have been transferred this year or next. Listing these three companies in the order in which their surplus to policy holders exceeds their re-insurance (unearned premium) liability, they appear as follows: Aetna Life Insurance Company, 399%, Yorkshire Indemnity Company, 337% (since increased to 355%) and Aetna Casualty and Surety Company, 226%. This comparison is not intended to reflect in anywise upon the financial position or stability of the Aetna Casualty and Surety Company. It is made merely to indicate the relative position of the Yorkshire Indemnity Company.

In taking over the Group Plan, the Yorkshire Indemnity Company assumes all of the terms of the arrangement under which it has been operated in the past. The expense ratio will remain at its present level for the time being and every effort will be made to reduce it. Loss reserves will be established on a per-case basis as before, but the total will be adjusted so as to give recognition to the average cost of suits and claims closed. In addition, several important and valuable improvements have been incorporated in the arrangement which for one reason or another were not possible in the Aetna.

Arrangements have been made so that members may secure protection on account of the use of regularly employed assistants or technicians by an endorsement added to their individual certificates. Provision has also been made to cover the employment of temporary or emergency substitutes in the same manner at a cost of one-half that charged heretofore for permanent assistants.

The Company has agreed to furnish the Society with a loss voucher form covering each suit or claim closed with a complete analysis of all expenditures in connection therewith. At the conclusion of each case, this form will be prepared in triplicate and sent to the legal counsel of the Society to be checked and approved. One copy will be retained by him, one sent to the insurance representative of the Society, and one returned to the Company. No charges will be made against the Group Plan except from approved vouchers. This system will not only furnish a check upon the losses charged to the Society's experience, but will furnish data from which it will be possible to make any sort of loss analysis which might be required in the future.

Beginning January 1st, the cost-plus provision in our insurance arrangement will be extended to include premiums collected from and losses charged to the higher brackets of

insurance, instead of being limited to the minimum or base policy as heretofore, and a full accounting of all transactions will be made.

In order to take care of the business during the period while the transfer to the Yorkshire is being made, the Aetna has agreed to issue both new and renewal policies up to December 31st and to carry such policies to expiration during the year 1936. Policies expiring on or after January 1st, will be renewed in the Yorkshire as they expire. This will in no wise jeopardize or affect actions pending under Aetna policies or protection against suits which may arise at any time in the future for acts committed by an insured member while his Aetna insurance was in force.

A further matter in which interest is being expressed at the moment, is the question of the elimination of company agents and independent brokers through whom some of the members have secured their insurance under the master policy. After January 1st, certificates of insurance in the Group Plan can be obtained only through the insurance representatives of the State Society. This was the original intention when the Plan was organized and is an arrangement which the Insurance Committee has long felt was necessary for the protection of all concerned.

Our insurance representative is charged with responsibility to the Society for the proper handling of all details of operation and for seeing that all terms of the arrangement by and with the insurance company are fully carried out. Under the present method of handling, it is as impossible for him to assume responsibility for transactions handled by the Company through local agents or brokers, as it would be for our legal counsel to be responsible for the defense of a suit delegated by the Company to a local attorney. Furthermore, local agents or brokers are not interested in the troubles of the State Society and usually know very little about malpractice insurance or the requirements of the Group Plan. No company agent or independent insurance broker has been responsible for or contributed to the success of the Group Plan. Their activities have been limited to securing applications from members in many cases without sufficient knowledge of the business to advise them correctly when the applications were made, and none of them have been able to render assistance after a loss occurred. For this "service" agents and brokers have been paid commissions varying from 10% to 17½% of the premium, and that expense has been charged to the Group Plan operations.

Our insurance representative will travel throughout the State and, on request of com-

ponent county societies, will give all members, requiring it, expert advice on all matters pertaining to their malpractice insurance problems. With the elimination of agents and brokers, a further reduction has been made in the acquisition cost charged to the Group Plan, and when the new operations have been worked out and stabilized, further reductions will be possible. It is upon economies of this kind, as well as reductions in loss costs, that the Society hopes to lower the final cost of insurance, and all members are urged to support these efforts.

The benefits which will accrue to members from the new arrangement with the Yorkshire may be recapitulated as follows:

1. Our rate will remain the same as at present, and provided there is no marked increase in the number and cost of suits and claims disposed of, we can look forward to a reduction rather than an increase of cost.
2. There will be no increase in the expense ratio and further economies have been made, which it is hoped will reduce rather than increase that item.
3. The manner of establishing loss reserves for rate making will recognize the average cost of suits and claims closed.
4. The cost and profit agreement, under which the Plan is operated and upon which rates are computed, will extend to all limits of insurance instead of being confined to the minimum limits or base policy as heretofore.
5. The surcharge for x-ray therapy protection will be reduced 18 per cent.
6. The Society will be furnished complete data as to income and disbursements in such detail that total tabulations may be checked and losses analyzed as a whole or by any classification desired.
7. The old cumbersome method of covering the employment of assistants or technicians has been replaced by a simple endorsement to be added to the members individual certificate.
8. A much needed provision for covering members on account of the acts of temporary or emergency substitutes has been made at one half the cost of similar protection on account of regularly employed assistants. The importance of this provision should not be overlooked as this coverage is needed by a large majority of the members and they have been totally without it in the past.
9. All details of operation will be centralized in the insurance department of the Society. Such centralization is necessary in any group undertaking if group unity is to be maintained and group influence exerted.
10. Last but not least, we have associated with us and standing behind the Group Plan a high grade, sound, smaller company, composed of men of fine character and ability to whom the competent and economical operation of the Group Plan will always be a matter of first importance.

While the termination of a contract of

fourteen years' outstanding with an honorable partner, such as the Aetna has been, is a serious matter and a step that could not be taken lightly, no one can properly appraise the situation as outlined in these notes or recognize the advantages that will accrue to the Group Plan without a feeling of satisfaction and confidence in the transfer which the Society has decided to make.

At this point, it might be well to warn members who want their insurance renewed on time, not to delay completing and returning to Mr. Wanvig the new blue Yorkshire application blanks as soon as they are received from him. These are being sent out 90 days ahead of time, as it requires several months to complete the renewals. When members receive these new forms there will appear to be plenty of time before their current insurance expires, but in order to continue their protection without a break, the applications should be completed and returned at once.

In the matter of loss costs this opportunity is taken to repeat and emphasize what our legal counsel has so often said *that somewhere in the neighborhood of 60 per cent of claims against members are inspired by thoughtless, hasty and sometimes deliberate criticism of doctors by fellow practitioners.* Every malpractice action is inspired by, based upon or aided by the opinion or testimony of a doctor, and, in the majority of

cases by members of the State Society. That a member's honest professional opinion and testimony must always be available to his patients goes without saying, but the number of unjust and groundless suits which have been brought against members leads to the conclusion that the medical advice upon which they were based did not correctly represent the full circumstances regarding the case or the doctor had a poor conception of the duty he owed to the profession. Such suits are always won for the defendant, of course, but the cost of winning them is charged to the Group Plan and paid for by the members in their insurance premiums.

For fourteen years the Group Plan has held together the malpractice insurance situation in New York and prevented the high costs and chaotic conditions that most certainly would have existed without it. It stands as a monument to the wisdom and foresight of the State Society, and no one can examine its history or the extent to which it is controlled for the benefit of the members by the Society through the Executive and Insurance Committees and insurance representative without a feeling of comfort and security in the protection which it offers for the future.

Medical News

Albany County

A REGULAR October meeting of the Medical Society of Albany County was held on Wednesday evening, October 23, 1935. Doctor Arthur J. Wallinford read an interesting paper on auto blood transfusion. The discussion of this paper was opened by Doctor Lyle A. Sutton.

The second paper was "The Differential Diagnosis of Hyperthyroidism" by Doctor John C. McClintock. The discussion of this paper was opened by Doctor George E. Beilby.

The following new members were elected to the Society: H. Charles Goldberg, M.D., Syracuse University, 1922; Hugh Francis Leahy, M.D., Albany Medical College, 1932; W. L. J. McDonald, M.D., Queen's University, 1933; Peter D. Comanduras, M.D., Tufts College Medical School, 1933.

Chemung County

A SPECIAL MEETING of the Chemung County Medical Society was held on September 11th in the library of the Arnot-

Ogden Memorial Hospital. After other business was completed, the President introduced Dr. G. C. Vogt, of Binghamton, President of the Broome County Medical Society and also a member of the State Economics Committee. Dr. Vogt stated that the New York State Medical Society was to make arrangements whereby physicians who had qualified under the new Compensation Act would be eligible for the treatment of Welfare cases, Transient cases, WPA and other Federal Medical Cases, in their respective communities, and that one of the principles in this arrangement would be free choice on the part of welfare clients. He stated that the fee schedule would probably be ready about November 1st. He strongly advised a local County Welfare Advisory Committee. He pointed out that in Binghamton, physicians on service in the hospitals were paid \$15 for a minor operation and \$25 for a major operation, \$25 for a delivery, \$10 for an anesthetic, and \$1 per call per patient on all County Welfare Cases, and he felt that we are

entitled to the same fees. Dr. H. I. Johnson, Chairman of the Compensation Commission of Broome County, next made a few remarks about the Compensation Act and its workings and replied to various questions. At the request of the President the Secretary then read the salient features of the "Gradient Plan", and illustrated with lantern slides the details of this plan. The plan was further discussed by Dr. Vogt and various members.

Columbia County

DR. R. P. HARRIS, of the Columbia Country Club, brought the first Hudson River Gold Association championship to Hudson since the days of Harold Wood, when he won the annual senior championship held on the Powelton course at Newburgh on September 19th.

Playing in rare form against golfers from nine other clubs in the Hudson Valley district, Dr. Harris toured the difficult 18-hole layout at the Hilly City in 78 on his first day out. His second round started out well, with a first nine of 39, but the first three holes on the homeward nine tripped him and he scored 42 for a total of 81. With his 78 of the previous day, Dr. Harris' total of 159 is the lowest score in years in this tourney.

Greene County

AT THE 129th annual meeting of the Greene County Medical Society on Oct. 8 at the New Walters' Hotel at Cairo, Dr. Frederick W. Goodrich, of Catskill, was unanimously elected president. Other officers elected were as follows: Vice President—Dr. Earl T. McQuade of Coxsackie, Secretary—Dr. William M. Rapp of Catskill, Treasurer—Dr. Mahlon H. Atkinson of Catskill, Chairman of Legislative Committee—Dr. P. G. Waller of New Baltimore. Chairman of P. H. and P. R. Committee—Dr. Alton B. Daley of Athens. Delegate to State Society—Dr. M. K. Colle of Catskill. Alternate—Dr. W. H. Freeman of Ashland.

An interesting address on the new law as to treating employees under compensation, was delivered by Dr. Lewi Donhauser of Albany. W. H. Grey explained in detail the new law as it affected physicians treating injured persons under compensation.

Kings County

IN AN EFFORT to widen the scope of nursing service in Brooklyn, the nursing committee of the Kings County Medical Society has circulated a questionnaire among society members interested in the nursing situation.

Dr. Alec N. Thomson of the society announced that the survey was entirely un-

official, but added that the committee's findings might spur the Kings medical unit to take some constructive action toward improving nursing conditions.

Many Brooklyn physicians believe, Dr. Thomson said, that there would be fewer pneumonia and other fatalities if patients only knew that nursing was available at low cost.

The King's Society's nursing committee believes it would be possible so to disseminate publicity on nursing possibilities that the public would respond by employing nurses, lightening the task of the doctors and giving the patients themselves a better chance to recover more speedily from their illnesses.

Dr. Thomson conceded that such a publicity program, if carried out, might tend to reduce the amount of hospital care and increase the amount of home care, since patients frequently are kept from obtaining proper treatment by fear of hospital costs.

MEMBERS OF THE KINGS COUNTY Medical Society have been warned to notify police and the State and City Departments of Health whenever they see blood pressure reading being given gullible persons by laymen in drug stores, and in penny arcades where concessions, according to the society, have been let out to quacks.

The only value in having blood pressure readings taken is to guide physicians in treatment of patients. The amount the reading registers, even though the layman does not believe his pressure normal, does not always make much difference.

Blood pressures taken by unlicensed people should not be permitted, for they do nothing except frighten a person in one instance, or lull him into a dangerous sense of security in another.

Monroe County

CHILDREN'S HEALTH HOURS may be established by Rochester physicians as part of their regular office practice in the near future. The Public Health Committee of the Medical Society of Monroe County has approved the recommendations of the Child Welfare and Tuberculosis subcommittees of the State Medical Society to undertake a new program of information to the profession.

The plan was outlined before the state medical group in Albany recently by Dr. Edward G. Whipple and provides for the setting aside of a period during which physicians will give protective treatment, including smallpox vaccination, diphtheria immunization, diagnostic tests including the tuberculosis skin test and periodic examinations.

Nassau County

DR FRIDERICK C HOLDEN, obstetrician and gynecologist at the Bellevue hospital, New York City, was the guest speaker at the scientific session of the Medical Society of the County of Nassau at the Nassau Bar Association Home, Mineola, on Sept 24.

Dr George A Newton of Freeport, president of the society, welcomed seven new members.

New York County

CERTIFIED MILK PASTEURIZED was placed on sale for the first time in the metropolitan New York area in October, it was announced by Dr James A Tobey chairman, committee on public relations of the Metropolitan Certified Milk Producers, Inc., following a meeting of the New York County Medical Society Milk Commission held at the office of Dr Walter Lester Carr, Secretary of the Commission, 112 East Seventy-fourth street.

At its meeting, the New York County Medical Society Milk Commission voted approval of the sale of certified milk pasteurized in New York County. Similar approval has been voted previously by the Milk Commission of the Medical Society of the County of Kings, by the Hudson County, N J Medical Milk Commission and by other commissions of the metropolitan area. Producers of certified milk in this area offered the new product while continuing to sell the regular certified milk.

Oswego County

THE MEDICAL SOCIETY of Oswego County met on Oct 15 at the Elks Club in Oswego for its 115th annual session and listened to interesting papers by Leon A Sutton, MD, FACS of Syracuse on "Local Anesthesia in Minor Surgery," and Frederick S Wetherall, MD, FACS of Syracuse, chairman of the Fifth District Economic Committee, on "Present Day Problems in Medical Economics."

Queens County

DR MORRIS BENDER, President of the Queens County Medical Society, opposes the plan of the Works Progress Administration to obtain employment for colored women as housekeepers and practical nurses in the homes of relief recipients who are ailing or infirm.

Pointing out that under present relief regulations any ill person must be sent to the hospital after five days, Dr Bender said:

If this is purely a maid service or a house keeping service I can see no objection to it but I would object to any infringement on the

nursing profession. The plight of the unemployed nurse in New York City is a very serious one at the present time. There are thousands of such nurses around the city for whom any sort of relief would be a Godsend. In many cases they have had to take any kind of work in order to live.

He said the matter would be discussed at the next meeting of the Queens Medical Society, when more information on the PWA plans would be available.

Schoharie County

DR RAEBURN J WHARTON, major in the United States Army medical officers reserve corps and president of the Binghamton Reserve Officers' Association, addressed the Schoharie County Medical Society, Oct 8, at Cobleskill on "Anorexia in Childhood."

Suffolk County

DR CHARLES MILLER at the first showing of his turkeys at the Suffolk County Poultry Show, carried away the blue ribbon of the Turkey Section. Which lends the Bulletin of the Queens County Medical Society to remark:

"The psychiatrists tell us that we should all have hobbies to offset the psychic shocks incident to our daily lives. Not all of us, however, pursue our hobbies with equal success. Thanksgiving Day is not so far off so we wish Dr Miller continued success in his efforts."

Ulster County

THE ULSTER COUNTY Medical Society held a regular meeting on Oct 24 at the Governor Clinton Hotel in Kingston. The meeting was attended by a large number of doctors who represented all parts of the county. Routine business was transacted.

Wyoming County

THE ANNUAL MEETING of the Wyoming County Medical Society was held at Warsaw, October 9th. The following officers were elected for 1936: *President*, Dr C H Harville, Warsaw; *Vice President*, Dr G W Nairn, Warsaw; *Secretary-Treasurer*, Dr O T Ghent, Warsaw; *Delegate to the State Society*, Dr L L Klostermyer, Warsaw; *Alternate*, Dr Henry S Martin, Warsaw.

The scientific meeting was devoted to a discussion of Pneumonia by Dr Nelson G Russell, Professor of Medicine, Buffalo Medical School. Points in diagnosis were thoroughly discussed including the demonstration of rapid typing methods. Treatment was discussed with special emphasis on newer methods of treatment including serum and oxygen administration and the use of pneumothorax.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Malpractice—Removal of Uvula During Tonsillectomy

A case decided a short time ago in a nearby jurisdiction* is an interesting example of the application of the rule that in a malpractice case where negligence is proved, injuries actually resulting from that negligence must be shown to hold a doctor responsible in damages.

The case arose out of the removal of the tonsils of a child six years of age. The patient was one of several who were assigned to Dr. S. for operation under his care. The actual operation was performed by a fifth-year medical student not licensed to practice who was an interne at the hospital, but the interne was actually supervised by Dr. S. During the operation the dissection was followed by a hemorrhage which was more severe than anticipated and the bleeding caused the child to choke and gag. The result was that the patient's uvula became engaged in the snare, and the operative field became obscured, so that when the interne operated the snare to remove the tonsil a portion of the uvula was also removed. At that stage in the operation Dr. S. stepped in and applied a sponge and sutures to stop the bleeding. He also proceeded with the removal of the second tonsil, and again a hemorrhage developed and further suturing was necessary.

Subsequently an action was brought against Dr. S. on behalf of the child, charging that he or some person under his supervision and control had been negligent in the performance of the operation and that as a result it was claimed that the child had suffered certain injuries. The plaintiff specifically claimed that the child as a result of the operation had lost her sense of taste, and that her speech had become harsh with a nasal tone, and further that she was unable to properly swallow food.

Upon the trial there was testimony in behalf of the plaintiff from which it might be interpreted that the precautions usually taken to prevent the uvula from becoming engaged in the snare had not been taken upon the operation. The question that developed as the main point involved in the case was whether, assuming negligence, there were any actual damages resulting from such negligence.

The medical witness called on behalf of

the plaintiff testified that he had examined the child, and had found only a part of the uvula missing. He admitted in the course of his testimony that he really did not know the function of the uvula, and gave the following answer:

"Q. Doctor, this uvula is not important?

"A. It is not causing her trouble, not the uvula; it is not the uvula that is at fault."

The defendant's expert gave in part the following testimony on the trial:

"Q. Tell me, doctor, looking into that little girl's throat, do you see anything there to prevent her swallowing?

"A. No, I do not. I think she can—she may have a little stiffness for a time, that is a thing we see at times following an operative procedure. It is a bit more likely to come in an adult, but even in children who have had some throat inflammations, for quite a little time they will have a little difficulty in swallowing, not marked. . . . I do not believe that the uvula has been a factor in this case at all. I think your problem that you are dealing with is a matter of the scar associated with the suturing to control hemorrhage.

"Q. Let me understand the hemorrhage results, does it, from the dissecting?

"A. Results from the dissection.

"Q. And it is increased, or is the amount of the suturing increased, by the removal of the uvula?

"A. No.

"Q. Then I want to know how much effect upon the child's present condition the getting of uvula into the snare and the removal of the uvula has had?

"A. I do not believe that that feature has anything to do with it. I really think that the difficulty that she is complaining of and which has been more persistent than most—I will grant that—is not due to the removal of the uvula at all, it is due to the matter of the control of hemorrhage, and the necessity of putting the sutures pretty deeply to control that. It is not the result of the removal of the uvula. . . . If you look in there and see the uvula amputated, they think, well, that looks funny, and frequently there is some statement made about it, but I honestly believe that so far as the patient is concerned it has absolutely no damage."

The Trial Court determined that no damages properly attributable to the claimed negligence had been proved under the negligence, and therefore, dismissed the action. An appeal was taken from the judg-

* McNamara v. Smith, 2 D. L. R. 1934-417.

ment of dismissal and the Appellate Court after reviving the case affirmed the lower Court's ruling. In the course of its opinion the Court said:

Unless therefore substantial damages can be awarded, the judgment of the learned trial Judge should not be disturbed.

From the evidence there would seem to be no doubt that the infant plaintiff has suffered certain disabilities. But the evidence makes it clear that these did not result from the loss of the uvula nor from any increase in the amount of suturing necessitated by its removal.

The Court further said, commenting upon the testimony of the experts:

This witness (defendant's expert) might, perhaps, be suspected of partiality, but the evidence of Dr. T., called on behalf of the plaintiff is almost equally negative. He said, "It is not causing her trouble, not the uvula; it is not the uvula that is at fault." No witness was found to attribute the child's disabilities to the loss of her uvula or to any increased suturing necessitated by its removal. Nor did any witness say, nor must it be assumed, that the uvula is by itself of any specific importance. The farthest Dr. T. would go in this respect was to say that if the uvula were totally removed . . . "it might interfere with the action of the palate."

In an action for negligence, the plaintiff must prove not only that there was negligence but also that any injuries complained of were the direct result of such negligence. In this case the learned trial judge found that the plaintiffs had failed to do this, and in view of the evidence it is impossible to say that his finding was wrong.

Electro-Coagulation of Tonsils

A middle aged man consulted a physician, specializing in ear, nose, and throat work, with respect to complaints of rheumatic pains in his legs. The doctor examined him and found that he was suffering from hypertrophied and diseased tonsils and suggested their removal. As the man did not desire to be prevented from attending to his occupation arrangements were made whereby the doctor undertook to treat him by the electro-coagulation method. It was explained that a number of such treatments would be necessary. Several electro-coagulation treatments were administered over a period of two months and at the end of that time the patient consulted the doctor with respect to a hemorrhage from his right nostril. He saw the patient for a few days with respect to that condition and it subsided, and explained to the patient that further electro-coagulation treatments should be resumed in a short time. The patient did not return for such treatments although the doctor saw him on a subsequent occasion when it was agreed between them that the treatments should be resumed. The doctor never made any repre-

sentations to the patient that the tonsils had been completely removed by diathermy.

After considerable time had elapsed the doctor instituted an action against the patient to recover the amount of his bill. The patient interposed a defense and counterclaim charging that the plaintiff had committed malpractice in the treatment which he had rendered. The case came on for trial as a non-jury case and the patient established that subsequent to the treatment which the plaintiff doctor had rendered he had gone to another doctor who had removed the remaining portions of the tonsils. He tried to establish that he had been discharged as cured by the plaintiff.

At the conclusion of all the testimony the Court rendered a verdict in favor of the doctor for the amount of his bill and dismissed the counterclaim of malpractice.

Recurrence of Gall Stones

A young married woman was referred to a physician who had for many years specialized in general surgery. Examination led to a diagnosis of cholecystitis and appendicitis and operation was advised. X-rays and pathological tests confirmed the diagnosis. An operation was performed which consisted of the removal of the appendix and gallbladder through an upper right rectus incision. The appendix was found swollen, chronically inflamed and adherent to the omentum. A large stone the size of a marble was found in the cystic duct and the gallbladder and the stone were removed. The ducts were carefully palpated by the surgeon and no other stones were found. The patient remained in the hospital about three weeks and had an uneventful recovery.

Sometime later it was reported to the doctor who had performed the operation that the patient had been operated on by another doctor for the removal of other stones.

A malpractice action was brought against the surgeon in which the principal claim was that in the performance of his operation he had failed to remove all of the stones and that a subsequent operation had become necessary. It was also claimed that at the time he operated the surgeon was himself not in sufficiently good physical condition to properly perform the operation. The reason for the latter charge apparently was that sometime subsequent to the performance of the operation the defendant became invalided. Before the case could be reached for trial he died. Application was made to the Court in order that the case might be marked abated by reason of defendant's death. Thereupon plaintiff's attorney consented to discontinue the action.

Across the Desk

"Nuts, Squealers, and Regulars"

SOME OF THE CRIPPLE CREEK DOCTORS used to come to the meetings of the local medical society in the good old days with their six-shooters in their belts, and slept with the trusty guns under their pillows. To many of them "hard likker" was their social tea, and water belonged under bridges, but they were men of practical ability and supreme professional loyalty—in short, "they were God's own people," declares a doctor who knew them well and is now president of the Colorado State Medical Society, Dr. Walter W. King, of Denver.

He recalls in his presidential address the remark of a Leadville miner, that there are three kinds of poker-players: "Regulars," "squealers," and "nuts," and he proceeds to say that this is not a bad classification of the members of a Medical Society!

A statement like that looks as if it were good ground for a libel suit, a fight, or a foot-race, so it may be just as well to hasten on and tell what Dr. King means by it. It is not so bad as it seems. The nuts, it appears, are the research men, the animated interrogation points who dig deep into the unknown. They are "curious cusses," he says, and few in number, but they think, they ask strange questions, and they are the main source of the progress of medicine. They spend their energies tirelessly to make the world a better place to live in.

If those are the "nuts," what are the "squealers?" Well, they are the reformers. They like wild cards in the game. They call for a new deck. But we are warned not to get the idea that the squealers are not of value. They are the yeast in the wholesome bread of improvement, he says. True, they are complainers, but their criticism stimulates advancement. We should be in a bad way, a backward way, a way of stagnation, without them. Dr. King owns up that he is a "squealer."

The largest group are the "regulars." They call for no new decks or new games. No deuces wild for them, and "if the joker is used at all, it is only for aces, straights, and flushes." They are the backbone of the society. They are the "organization men" who give their time without stint, their effort and their money to keep the wheels of the organization going around. If they are called "the clique," they laugh it off and go on working for the good of all. They are the wheelhorses, always at the meetings, always ready to do their bit.

While others are telling what should be done, or are ready to boss the job, these men are ready to do the real work.

Is the Profession "Over-organized"?

SOMEWHERE AMONG THE CLASSES so pungently described by Dr. King must be the men who like to form new medical societies, for the number has multiplied to the point where Dr. Olin West, Secretary and General Manager of the American Medical Association, declared in an address that "we face a very dangerous problem in the fact that in a certain sense the medical profession is over-organized." It is a grave danger, as he sees it, because it brings a dissipation of fealty, a duplication of effort, a confusion in the public mind, and encourages propaganda of a destructive sort. He admits freely that some of these organizations fill a very useful purpose, but fears that the multiplicity of medical societies is really growing to be more of a detriment than a help.

Take actual examples. In one city of less than 300,000 Dr. West found an average of 29 medical meetings a week, as contrasted with one meeting of the county medical society a month. Was the county society helped or hurt by this situation? In another city of less than 400,000 there were 42 medical meetings a week, and the county society, "if it was lucky, got one meeting a month." Worse yet, in some places he found that the staff meetings of hospitals had been substituted for the scientific meetings of the county medical society, so that many members of the county society were cut off from all share in the scientific work. This situation he calls "dangerous to organized medicine," and he asks for our "careful, prayerful consideration" of it.

The basic medical organization in this country, of course, is made up of the county and state societies and the American Medical Association, and whatever helps that basic structure helps the profession; whatever hampers or weakens it injures the profession. There can be no question that many of the societies discovered by Dr. West are doing invaluable work in their own fields, of a sort that could not well be done in the county bodies. But 42 medical meetings a week in a city of 400,000 looks a bit excessive to the casual onlooker. It recalls the wife who asked a divorce because her husband was a "jiner." He "jined" so many lodges that he was never home. It is a mental bent that some have. It may explain why various county meetings are not better

supported. Perhaps it is time for surveys of the situation in our cities and counties to see if we are over-organized.

Big Man, Big Illness

THE TYPE OF MAN is familiar in this great land of ours who must always have something bigger than anyone else. His car must be grander, his house more palatial, his wife more bejewelled, than any other. But a Detroit magnate gives the type a new wrinkle. He thought he was too important to have a little illness—it just must be something serious. You don't believe it? It is set down in black and white in the *Medical News* of the motor city, where it happened. This important individual had a case of the "jitters," to use everyday lingo. He was highly nervous and irascible, due to loss of sleep and appetite. He needed a rest. His doctor took his blood pressure, listened to his heart, and prescribed mineral oil, sedatives, and a vacation. The magnate was furious. He knew he must have something very, very grave. So he called another doctor. Same verdict, same prescription, same rage. He saw another medical man, and another, and another, five in all. All prescribed mineral oil, sedatives, and a vacation. Total cost, \$25.

So he traveled many miles to a well known clinic, where his history was recorded at enormous length and, completely disrobed, he ran the gamut of inspections, palpations, auscultations, and percussions from head to foot. He spent hours in the x-ray and clinical laboratories. Specialists of assorted types scrutinized him with deep solemnity. At last, the verdict. He was advised to return in six months, to take mineral oil, sedatives, and a vacation. Total cost \$300, plus traveling expenses, plus hospitalization, plus a week's absence from business.

But he was satisfied. True, he did not have the grave illness, but he had gone through an examination worthy of his greatness and paid a bill suitable to his position in life. The next motor magnate who calls one of these five Detroit doctors will have an examination that will probe everything except the secrets of his conscience. The big man may not have a big

illness, but if he wants the other details large, he can be accommodated right at home.

"War Madness" Psychoanalyzed

THE SUPPER-PATRIOTS and 100-per-centers who want war declared at the drop of the hat have been psychoanalyzed by a group of no less than 339 psychiatrists of 30 nations. They warn us that the world may be pushed into a "war psychosis" if we do not resist. "There is in the world a mentality which entails grave dangers to mankind," they declare in a signed statement which has been sent to leading statesmen particularly in Europe, where this form of insanity seems all too common. The document is sponsored by the Netherlands Medical Association, which has followed it up by forming a "Committee on War Prophylaxis." Two Italian doctors, among others, have had the courage to sign the statement. Professor Dr. M. L. Bianchini, lieutenant colonel in the Italian Army reserve, and Professor T. del Greco, director of a psychopathic hospital in Aquila, Italy. American signers are Dr. Charles Macfie Campbell of the Boston Psychopathic Hospital, Dr. Alfred Gordon of Philadelphia and Dr. A. J. Rosanoff of Los Angeles.

The root of the trouble is the fact that the primitive fighting instincts of our savage ancestors still lie only a little below the surface of our natures. "Civilized, twentieth-century man still possesses strong, fierce, and destructive instincts," we are warned, "which have not been sublimated, or only partly so, and which break loose as soon as the community to which he belongs feels itself threatened by danger."

The savage instincts are easily roused by incendiary utterances of statesmen hungry for fame and power. When the war-shouters and flag wavers get into the saddle, then the people "become neurotic." "They may be carried away," declare these mental experts, "by hallucinations and delusions, thus involving themselves in adventures perilous to their own and other nations' safety."

If we have reached the point where war-madness is recognized as madness, that is something anyway.

"PANEL" TROUBLES

In Germany panel physicians who have been holding special office hours in clinics or hospitals have been compelled to give them up, under the rule that no doctor may have more than one place of practice. The rule even bars a doctor from opening a second office in a town having no physician. A startling case of wholesale recovery is

reported from Germany when inspectors were sent to find out if workers drawing sick pay were really sick. It seems that 2,008 were ordered to appear for examination. Eight hundred sixteen of them at once declared their complete recovery, 289 were found to be well. So nearly half of them were not ill at all.

Books

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Principles and Practice of Preventive Medicine. Edited by C. W. Hutt, M.D. and H. Hyslop Thomson, M.D. Two volumes. Quarto, illustrated. London, Methuen & Co., Ltd. 1935. Cloth, £3-13-6.

International Clinics. A quarterly of illustrated clinical lectures and especially prepared original articles on Treatment, Medicine, Surgery, Neurology, etc. Volume 3, 45th Series. 1935. Edited by Louis Hamman, M.D. Octavo of 337 pages, illustrated. Philadelphia, J. B. Lippincott Company. 1935. Cloth. \$3.00.

Textbook of Attendant Nursing. By Katharine Shepard, R.N. and Charles H. Lawrence, M.D. Octavo of 433 pages, illustrated. New York, The Macmillan Company. 1935. Cloth. \$3.00.

Public Health Administration in the United States. By Wilson G. Smilie, M.D. Octavo of 458 pages, illustrated. New York, The Macmillan Company. 1935. Cloth, \$3.50.

Human Pathology. A Textbook by Howard T. Karsner, M.D. Fourth edition, revised. Octavo of 1013 pages, illustrated. Philadelphia, J. B. Lippincott Company. 1935.

I'd Live It Again. By Lieut.-Col. E. J. O'Meara. Duodecimo of 324 pages, illustrated. Philadelphia, J. B. Lippincott Company. 1935. Cloth, \$2.50.

A Treatise on Medical Jurisprudence. By Benton S. Oppenheimer, LL.B. Duodecimo of 290 pages. Baltimore, William Wood & Company. 1935. Cloth, \$4.00.

The Doctor and the Public. A Study of the Sociology, Economics, Ethics, and Philosophy of Medicine, Based on Medical History. By James P. Warbasse, M.D. Octavo of 572 pages, illustrated. New York, Paul B. Hoeber, Inc. 1935. Cloth, \$5.00.

The Story of Medicine in the Middle Ages. By David Riesman, M.D. Octavo of 402 pages, illustrated. New York, Paul B. Hoeber, Inc. 1935. Cloth, \$5.00.

I and Me a Study of the Self. By E. Graham Howe. Duodecimo of 256 pages, illustrated. London, Faber & Faber, Ltd. 1935. Cloth, 7/6.

The Medical Formulary and Prescription Manual. By Morris Dauer, Ph.G. First edition. 16mo of 297 pages. New York, J. J. Little & Ives Company. 1935. Cloth.

Daily Log for Physicians. By Dr. Colwell. A Brief, Simple, Accurate Financial Record for the Physician's Desk. Quarto. Champaign, Ill., Colwell Publishing Co. 1936.

Practical Clinical Psychiatry for Students and Practitioners. By Edward A. Strecker, M.D. and Franklin G. Ebaugh, M.D. Fourth edition. Octavo of 705 pages, illustrated. Philadelphia, P. Blakiston's Son & Co. 1935. Cloth, \$5.00.

Diseases of the Nose and Throat for Practitioners and Students. By Charles J. Imperatori, M.D. and Herman J. Burman, M.D. Octavo of 723 pages, illustrated. Philadelphia, J. B. Lippincott Company. 1935. Cloth, \$7.00.

REVIEWED

Alcohol and Anaesthesia. By W. BurrIDGE, D.M. Octavo of 65 pages. London, Williams & Norgate, Ltd., 934. Cloth 2/6.

For a book of only 60-odd pages, *Alcohol and Anaesthesia* contains more than its share of stimulating and unusual views, many of them entirely opposed to the present theories of muscle and nerve physiology. According to the author, alcohol exerts an independent action of exaltation and depression on the same tissue at the same time. In order to explain these apparently paradoxical effects, he has abandoned the accepted conceptions and has elaborated another based upon the newer

work on colloidal systems. He prefaces his rather complex theory by stating that the properties of muscle and nerve must depend upon the colloidal system which constitutes them. Energy manifestation can therefore come from two sources: through what is known as aggregation changes and through adsorption changes. According to him, alcohol decreases the muscular excitation energy which is derived from the adsorption phenomena and increases that available in the colloidal aggregation state. Consequently it both stimulates and depresses, the resultant effect depending upon the state of the muscle previous to the administration

and other contributing factors. For example, in perfusing a heart with Ringer's solution, if the amount of calcium in the solution is sufficient to cause the heart to beat maximally, then on addition of alcohol, its stimulant effect is unable to manifest itself and only depression is noted.

The above is characteristic of the type of experiments performed and the reasoning indulged in by the author throughout the book. Numerous analogies and philosophical asides help to clarify the subject matter. Although the experimental data are by no means conclusive, still the theories elaborated make interesting and worthwhile reading, if only since they stimulate the desire to defend the current views discarded so peremptorily by the author.

DAVID I. ABRAMSON

Aids to Obstetrics. By Leslie Williams, M.D. Tenth Edition. 16mo. of 219 pages. Baltimore, William Wood & Company, 1934. Cloth, \$1.25.

This small pocket-size book of 220 pages gives a bird's-eye view of the internal generative organs, of pregnancy, normal and abnormal labor, and the complications of the puerperium.

It is surprising that in such a small book, the author is able to give such a good view of the subject. He eliminates all non-essential details, and uses simple, terse language for his descriptions.

The book is up to date in its theory and treatment, and it will be of great use in giving a brief summary of a large and intricate subject.

W. S. SMITH

A Decade of Progress in Eugenics. Scientific Papers of the Third International Congress of Eugenics, held at American Museum of Natural History, New York, August 21-23, 1932. 8vo. of 531 pages. Baltimore, The Williams & Wilkins Company, 1934. Cloth, \$6.00.

In this book we find a complete report of the proceedings and of the sixty-five scientific papers read at the third International Congress of Eugenics held in New York in 1932. Its contributors represent the four corners of the globe, and include such personalities as Osborn, Leonard Darwin, and Davenport.

The dissertations are, in the main, academic and lofty. And while, in some instances, certain practical suggestions are advanced to further the cause of eugenics, they are in most cases speculative; and include such measures as control of immigration, prevention of racial amalgamation, selective sterilization, and eradication of foci of infection.

That eugenics is a worthy branch of scientific endeavor goes without saying. That its importance is and was recognized for many centuries, in such diseases as hemophilia (long before the inception of eugenics as a branch of science) must also be admitted. But as to how far the teachings of eugenis in bettering the stock of humanity can be applied to actual practice or can reap for them positive results is another story which, in our present stage of civilized development, is extremely difficult to envision.

EMANUEL KRIMSKY

Human Anatomy, Double Dissection Method. By Dudley J. Morton. First and Second Dissections Quarto of 265 pages, illustrated. New York, Columbia University Press, 1934. Cloth, \$6.00.

The Double Dissection Method enables the student in anatomy to cover the subject thoroughly with a great saving in curricular time. This method is in use at the present time at the College of Physicians and Surgeons and in that institution it was necessitated by a change in the course in anatomy, from two, to one year.

The author stresses the importance of studying the body while dissecting with as little use as possible of the books.

The first volume gives instructions and spaces for notes, on the larger structures and organs of the body. The last 50 pages in this volume are devoted to space for the dissector to fill in as he carries on the dissection of the various parts of the body. The same idea is also incorporated throughout the volume which contains as well, black and white sketches where muscles, nerves, and so on can be drawn. There is usually a key sketch for this purpose. It would seem that this method of dissecting is an excellent one. The student is taught to think about the action of the structures he is dissecting, for instance; it is suggested that he analyze the different muscle actions of the joints of the upper extremities by various muscular efforts, as rowing, swimming, shot-put, and so on. Most of the basic ideas incorporated in this form of teaching are not new, but this is the first time, we believe, that they have been so well arranged in book form where they can be valuable to all students in anatomy.

The second volume covers the second dissection which is a more detailed study of particularly the nervous and vascular systems, for the student is at this time better able to co-ordinate the body as a living physiological unit.

The second volume follows a different regional sequence because it is devoted primarily to the various systems. The author

suggests the free use of atlases during the dissection by this method.

The second volume also follows the same method of note writing and sketching as in the first volume.

Unquestionably this is an excellent and simplified method of teaching anatomy and should be adopted universally in the medical schools.

HERBERT T. WIKLE

Outlines for Psychiatric Examinations.

Edited by Clarence O. Cheney, M.D. Octavo of 134 pages. Utica, N. Y., State Hospitals Press, 1934. Cloth, \$1.50.

This book of 134 pages is a revision and amplification of a similar guide edited by Dr. G. H. Kirby. Its origin may be traced back to Dr. Adolf Meyer who gave some helpful advice in recording psychiatric history and observations. This book is a guide to collecting historical data, physical and mental symptoms of adults and children, and formulating these data into a summary for interpretation, diagnosis and treatment.

One chapter is a descriptive classification of mental disease and finally there is a descriptive classification of problem children.

The book has served well the New York State Hospital physicians and is highly recommended to medical students and physicians in private practice who may have psychiatric interests.

A. E. SOPER

Disease, Gadfly of the Mind. By Wm. Allen Pusey, M.D. Octavo of 20 pages. London, H. K. Lewis & Co., 1934.

This is a most entertaining essay, written in the author's delightfully easy readable style, on disease as a stimulant of the mind. One may get an idea of the contents of the book from the following excerpts: "The human mind has had to develop itself. Man started at a cultural zero and had to find out everything for himself. The tracing of the making of the mind is, therefore, not a psychological or physiological, but a historical study of its progress. Thinking is not spontaneous because of the pleasure of intellectual exercise but because of prods from sharp necessity. Primitive man in the moments spared from the search of food speculated on how he could better preserve life. His endeavors to overcome injuries and disease were the first steps in medicine and no incentives to thought were earlier, or acted more continuously upon man's mind than his physical ills."

From then on the history and importance of medicine and particularly that branch of medicine, diseases of the skin, as a stimulant to the mind is traced.

Doctor Pusey shows that from the study

of the skin have been obtained our first knowledge of histology, pathology, bacteriology, contagion, infection and immunity, allergy and metabolism. Continuing, the author states that even now, when we may surely say that the mind has reached a stage of light, in knowledge of the physical world, the skin still furnishes one of the most fruitful fields of research, because it offers opportunity for searching out the finer facts of biology and pathology.

Doctor Pusey has made a study of the history of medicine and has written a splendid book on the History of Dermatology. Anything he contributes is always most interesting and instructive.

We highly recommend this booklet for a most delightful half-hour of reading.

ALFRED POTTER

Aids to Phychiatry. By W. S. Dawson. Third edition. Sexdecimo of 318 pages. Baltimore, William Wood & Co., 1934. Cloth, \$1.50.

This pocket-size book of 348 pages deals in clear-cut fashion with the different phases and types of mental disease and treatment. It is convenient for quick reference, and although diminutive resembles in its scope the larger reference books on psychiatry. It is surprising how exhaustively this small volume deals with the subject. Certain legal phases dealt with from the standpoint of the British Psychiatrist are, for that reason, more serviceable to him. There is little doubt of its value to the medical student and junior medical officers in a mental hospital.

A. E. SOPER

Standard Classified Nomenclature of Disease. Compiled by the National Conference on Nomenclature of Disease. Edited by H. B. Logie, M.D. Duodecimo of 870 pages. New York, The Commonwealth fund, 1935. Cloth, \$3.50.

This is a national nomenclature developed through the co-operation of 27 national societies and governmental bureaus. The confusing lack of uniformity in terminology created the need for a nomenclature, national in its scope. It takes into account both the etiology of the disease and the part of the body affected, making it impossible to state symptoms instead of making a complete diagnosis. There is a numerical index allowing the expression of every diagnosis by a code number.

The classification and nomenclature is undoubtedly more scientific and complete than any previous one. It has been installed in the record rooms of 120 of the most important hospitals in the country, including those affiliated with the leading medical colleges.

W. E. MCCOLLOM

TRICHOBEZOAR
(Hair-Cast of Stomach)CARLTON F. POTTER, M.D., *Syracuse*

Foreign bodies in the stomach are of frequent occurrence, but those composed of hair are so unusual that they are most spectacular.

These hair objects build up from a small nucleus and gradually become larger until they often fill the entire stomach cavity at which time such distress is produced that the individual is prone to seek medical or surgical advice. The size and shape of these objects vary, depending upon how much hair has been ingested and the length of time they have been in the stomach. Should two or more hair-balls be present, they may be found on removal, to be faceted. This is caused by the peristaltic action of the stomach rubbing the foreign bodies together. A single hair-ball or cast is the most frequent finding.

It is a well known fact that hair-balls commonly occur in animals, and it has been thought that these foreign bodies had considerable charm in warding off disease or acting as emetics in certain types of poisoning. Indeed, nature is kind to animals, causing expulsion by mouth of such irritating objects, thus emptying the stomach of materials not easily assimilated.

The hair-balls seen in the human are the result of the ingestion of certain substances, such as persimmon seeds, found particularly in Southern states, hair, nails, wooden objects, glass, etc. Hair eating is most frequently found in the adolescent female. This is readily understandable as the habit of putting the hair in the mouth, pulling it through the teeth or biting the

ends of their braided tresses, allows some of it to slide down the esophagus without much difficulty. Usually, these hair eaters are of a normal mentality. Insane persons, as a rule, eat more solid objects such as bits of wood, tacks, nails, glass, spoons, and other objects.

Hair-balls vary in size and shape, and long continued action of the gastric juice does not seem to affect the color or texture of the hair. Even when large masses of hair remain in the stomach for long periods of time, the individual does not seem to suffer a great deal, nor is her general health affected to any great extent. When these foreign bodies fill the stomach or act as a ball valve at the pylorus, nature rebels.

Pain is an early symptom together with some vomiting. If the mass is large, the individual complains that she is unable to eat as much as formerly. One of the earliest symptoms is the presence of an abdominal mass.

In these cases, a differential diagnosis must be made between carcinoma of the stomach, displaced spleen, floating kidney, fecal impaction, omental tumors, retroperitoneal hematoma or intragastric tumors. These hair masses may pass through the pylorus into the small intestine and cause an intestinal obstruction¹ and have been known to produce a perforation, resulting in death.²

It is a curious explanation which these hair eaters give for their habit. One stated that she ingested her hair because it was so nice.³ Another stated that for years she had been in the habit of eating the

*Read at the Annual Meeting of The Medical Society of the State of New York,
Albany, May 14, 1935*

combings of her hair and her sewing cotton ends to clear her tongue.⁴ Another confessed that she swallowed hers to make her voice clear.⁵ Another because she liked the tickling sensation produced by the hair in its transit to the stomach.⁶ Another adopted the method with suicidal intent.⁷ The case that I report absolutely denied that she had been eating her hair until she was shown a photograph of the hair-cast removed from her stomach.

This girl, 20 years of age, is of practically normal mentality, of Indian descent, residing on the Indian Reservation south of Syracuse. She was admitted to Crouse-Irving Hospital, Syracuse, N. Y., on September 24, 1934, her complaint being that about September 1, 1934, she began to have pain in the epigastrium, especially after eating, this pain radiating to the left of the navel. She also complained of indigestion and flatulence, vomiting occasionally, the vomiting and pain increasing.

Her past history showed that she had the usual children's diseases. Tonsils and adenoids were removed some time ago. Two years ago, she had erysipelas, was very sick and her hair came out. It has not grown in and she wears a cap on account of her baldness. She states she was never jaundiced and she denies venereal disease.

Her family history showed that her mother died of heart disease, age unknown. Sister and brother died of pneumonia, ages unknown. Her father, one sister and one brother are living and well.

Examination showed an adolescent female, 5 ft. 3 inches in height, usual weight 128 pounds, present weight 128 pounds. Eyes, ears, and nose normal, teeth in good condition. No evidence of enlarged thyroid, no enlarged glands. Chest well formed, expansion good. Heart,—no murmurs. Lungs,—no cough, no adventitious sounds. Blood pressure was 120/70. Pulse volume and tension good.

The abdomen was tender over the epigastrium with an oval-shaped mass in the upper left which could be easily outlined on percussion. There was no tenderness over the appendiceal area. There was no ascites and no hernia. The abdomen was soft.

Menstruation began when twelve years of age, was regular and without pain, with moderate flow for four days. There was no trouble in urinating.

There was no edema of the extremities; the reflexes were normal, there was no ankle clonus nor Babinski.

Blood examination on Sept. 26, 1934, showed hemoglobin, 45%; red cells, 3,150,000; white cells, 13,700 with a differential

count of large monos. 5%; small monos. 18%; neutrophils, 77%; color index 1.7. There was a marked variation in size of the red cells, some variation in shape. The red cells were poorly filled.

Blood examination on Oct. 5, 1934, showed hemoglobin, 45%; red cells, 3,510,000; white cells, 15,150 with a differential count of large monos. 5%; small monos. 20%; neutrophils, 75%. There was some variation in the size and shape of the red cells, the red cells being poorly filled.

Urine examinations Sept. 28.—Yellow, clear, 1024, acid, minute trace albumin, no sugar, few red blood cells, few pus cells. Calcium oxalate crystals and squamous epithelial cells.

Oct. 6.—Yellow, clear, 1025, acid, minute trace albumin, no sugar, few pus cells, amorphous matter.

Oct. 7.—Yellow, cloudy, 1030, acid, no albumin, no sugar. Few leucocytes and squamous epithelial cells.

Sept. 26.—Blood Wasserman was negative.

Oct. 5.—Gastric analysis: Free HCL 20; total acidity 55.

X-ray examinations: X-ray studies, both fluoroscopically and by means of films, were made on two separate occasions.

The barium mixture passed through the esophagus without any difficulty, no x-ray pathology being present. The barium entered along the lesser curvature side of the stomach, at first collecting in its upper portion and then was projected toward the greater curvature, apparently going around an intragastric mass. It was then seen to fill the pyloric portion so that there was a definite decreased density in the body of the stomach.

The stomach was found to be large in size (see Fig. 1), filling approximately one-quarter of the abdomen. The barium was seen to pass through the pylorus into the duodenum. There were no defects in outline of the lesser or greater curvatures. The stomach, at the five hour period (see Fig. 2), showed scattered fragments of the barium, assuming the appearance of a mass, the size and shape of the stomach.

The jejunum and ileum were of a normal patency and the peristalsis rapid. The appendix was not visualized.

At the twenty-four hour period, the colon was well filled with the barium mixture with no definite x-ray pathology noted. At this time, the stomach was well outlined with irregular patches of barium. At the forty-eight hour period (see Fig. 3), the stomach was still well outlined, its appearance being that of a cast of the stomach and one got the impression that the opaque medium was scattered through an intragastric mass.

The conclusion reached, following this examination, was that there was an intragastric mass present giving the typical fluoroscopic and film defect and distribution of barium, suggesting a hair-cast. No med-

Fig 2 Double meal Showing five hour stomach and twenty-four hour barium in colon Note typical appearance of stomach at five hours

Fig. 3. Double meal. Stomach forty-eight hours. Showing irregular distribution of barium, with colon at sixty hour period.

ical or surgical diagnosis was made before operation except from the x-ray findings.

On October 6, the abdomen was opened above the navel by Dr. W. L. Wallace and a large stomach filled with a large hard mass was found. The stomach was pulled outside of the abdomen, a vertical incision made in the fundus and a large hair-cast

ing it. The secretion was removed with gauze. A small amount of hair entered the first portion of the duodenum but was still connected with the main part of the hair-cast. It was black in color and of fairly hard consistency. Its weight was 16½ ounces. The hairs were arranged longitudinally, the esophageal portion corresponding

Fig. 4. Specimen of hair-cast showing unusual shape and comparative size.

removed with a towel clamp. The stomach wall showed no hypertrophy.

Examination of the specimen after removal (see Fig. 4), showed it to be the shape of the stomach and composed of hair with a fine layer of gastric secretion enclos-

to the shape of the stomach, while the duodenal end tapered off gradually to the pylorus. The specimen was an exact cast of the stomach. A better specimen could not have been obtained if the stomach had been filled with plaster paris.

The specimen measured 20 centimeters in circumference and $5\frac{1}{2}$ centimeters in diameter at the esophageal end; 20 centimeters in circumference and 7 centimeters in diameter at its middle portion; $14\frac{1}{2}$ centimeters in circumference and $4\frac{1}{2}$ centimeters in diameter near the pyloric end; 3 centimeters in circumference and one centimeter in diameter at the pylorus and 28 centimeters in length, measured along the greatest curved diameter.

Recovery was uneventful.

Conclusion

This case is reported (1) on account of its negative history. (2) The diagnosis could only have been made by x-ray examination. (3) The characteristic appearance and distribution of the opaque medium scattered through the interstices of the hair-cast, especially at the five-hour period. (4) The uneventful recovery of the individual.

BOOK REVIEWS

(For other reviews see pages 1218 and 1238)

Commoner Diseases of the Skin. National Medical Monographs. By S. William Becker, M.D. Duodecimo of 283 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

This book of slightly over 250 pages describes all of the commoner diseases of the skin rather briefly, paying more attention to the details of carrying out the therapy. The style throughout is that of the lecture before students, or a discourse before a diversified group of practitioners. The less common dermatoses that are to be considered in differential diagnosis, are presented with passing comment.

There are about eighty excellent illustrations scattered throughout the text. The closing chapter "Formulary" is extremely valuable. In it, under an alphabetical arrangement, the various drugs, or formulae, are listed; and the various considerations in the use of the drug, or prescription, are outlined.

E. ALMORE GAUVAIN

Abnormal Arterial Tension. By Edward J. Stieglitz, M.D. Duodecimo of 261 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

This monograph is exhaustive and presents in detail the present knowledge of abnormal arterial tension. General considerations of normal tension and its mechanism are given, followed by the etiology and symptoms of hypertension. The effect of

hypertension upon the cardiac, renal, and nervous systems are presented in separate chapters with treatment. The subject of hypotension is also discussed in its relation to surgery and shock. This volume is an excellent review of this difficult subject and gives the present day conception of the care of these patients.

HENRY M. MOSES

Diseases of the Chest. By J. Arthur Myers, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 385 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

In this small compact volume we have another excellent piece of work from the pen of Dr. J. Arthur Myers. Though small in size, it is quite comprehensive, covering a considerable field in diseases of the chest. Not only is tuberculosis in its various types embraced, but the most modern thoughts on the treatment of pneumonia, influenza, pneumoconiosis, new growths of the lung, bronchiectasis, pulmonary abscess, empyema, massive collapse of the lung, etc.

The book is not intended to be an encyclopedia of knowledge on these diseases, nor could it even be called a text book; but it is a very readable series of essays on various subjects of penetrating interest pertaining to diseases of the chest, and as such is a very valuable contribution to current literature on the subject.

FOSTER MURRAY

THE MYASTHENIC SYNDROME

Presentation of Case with Description and Discussion of the Findings in the Central Nervous System

CHARLES A. MCKENDREE, M.D., *New York City*
and
ABNER WOLF, M.D., *New York City*

The myasthenic syndrome is a well-established clinical entity that should be readily recognized when the symptoms and signs have fully developed. Very valuable contributions to the subject, both from the clinical and pathological aspects, have been made during the past thirty years, and it seems unnecessary to review the historical material, the conflicting pathological studies, and the descriptive clinical data in this modest report. Perhaps it will suffice to say that it is certain that in most instances, no noteworthy evidence of pathological alteration of the central nervous system has been found by competent observers. Altho lymphorrhages of the muscles have been found frequently,⁴ there is abundant material in which no muscular lesions have been reported. From the endocrinological point of view, the suprarenal,³ thymic,² parathyroid,⁵ ovarian, and pituitary glands have received a great deal of attention, and results that must be considered speculative from the angle of specific treatment, have been reported many times.

There is evidence that the myasthenic syndrome may follow epidemic encephalitis.^{8,9} However, it is still not known whether the clinical entity known as myasthenia gravis pseudo-paralytica is due primarily to disease of the central nervous system.

To date, as far as we are aware, no definite etiological factor has been established for the myasthenic syndrome. We recognize a set of symptoms and signs that constitute a clinical entity without etiological or pathological constants.

In this presentation, we shall not deal with treatment which has recently aroused so much interest. We recognize the fact that recoveries have occurred spontaneously without specific medication; that remissions are exceedingly common, and

that apparently endocrine therapy, irradiation of the thymus, strychnine in large doses, ephedrine,¹² glycine, and other drugs, have produced amelioration or a remission of symptoms.

We are presenting simply a case study with the necropsy findings without attempting to correlate the findings with the clinical manifestations in a specific way.

The case was first reported by one of us (McKendree) in the Meeting of the Section of Neurology and Psychiatry, at the New York Academy of Medicine, April 12th, 1927, and the patient was shown. At that time, the diagnosis of a post-encephalitic myasthenic syndrome was proposed. The bulk of the following clinical material was published in the *Bulletin of the New York Academy of Medicine*.¹⁴

The record of examination is that of October 18, 1926, and is followed by a general summary of progress, up to the time of death, on March 11th, 1930.

Patient, F. S., aged 21, single, female, occupation housework.* Admitted to the Neurological Institute of N. Y., October 18, 1926, A-12833H.

History

Chief Complaint, marked fatigability; date of onset of first symptom, February or March of 1919; character of the first symptom, general muscular weakness; onset, slow and insidious; course, progressive and then intermittent.

Illness: During the fall of 1918, the patient had a slight attack of influenza lasting about four days, and requiring only one day of bed-care, following which, she seemed to be perfectly well. During February or March, 1919, the patient began to experience generalized muscular weakness.

* Referred to one of us (McKendree) by the kindness of Dr. Robert E. Humphries.

Her first incapacitating symptom, after the onset of the gradual increase in weakness, occurred on March 1st, while walking down a flight of stairs, at which time her knees gave way and she fell down. She arose and walked, but felt weak. She walked home, a distance of eight blocks and during this effort, she was forced to rest at practically every block. She fell at least twice on the way home. Following the onset of the disturbance in February, she also noticed that in school, she could not read aloud as long as she could prior to this time, and in fact, she had to give up reading in one of the lower classes in school because she became so easily fatigued. She said that her tongue felt tense and that after reading, she could not enunciate well. After her experience of falling on the stairs and going home, she was forced to give up her gymnasium work because of the fact that she became extremely tired after the simplest form of exercise. At about this time she was under a mental strain studying diligently to attain graduation from school.

Following this onset, the symptoms progressed over the course of the next two years until, in the summer of 1921 she could take only a few steps without being obliged to hold the knees rigid in order to prevent falling to the floor. She could not feed herself on account of the weakness in her arms, her eyelids drooped and she stated that on account of the drooping of the eyelids, she felt very sleepy. She would fall asleep if she lay down at any time of the day. It was extremely difficult for her to talk, she could swallow but very little, and tired very easily.

Toward the end of that summer, while at the seashore, she began to improve, and enjoyed a general remission in the intensity of her symptoms. There was however a continuation of the easy fatigability, difficulty in reading and swallowing, and a reduction of the general activity which showed considerable variation. The variation might occur during each day, or definite changes might occur from one day to the next. She reacted very well to rest and improved considerably if rest was enforced. She had no idea what days were going to be good days, and the condition of weakness might come on within an hour.

During the summer of 1925 the patient spent her summer at the seashore; and on one day she felt unusually well, so that she could run and jump and even walked a mile alone. The remission was of very short duration, however, and the rest of the day, she felt as she had previously.

For a few years, the patient's eyes tired very quickly and when she became tired,

she experienced double vision, the objects being apparently side by side. The condition cleared up with rest. Direct forward gaze did not manifest diplopia except when she was very tired. For the same length of time she noticed a rather decreasing ability to look sidewise or vertically with any facility. Writing, walking, masticating and talking, in fact, every act consisting of continued muscular effort was greatly impaired.

In March 1926, she had a tonsillectomy, and following the operation, she remained in bed for 36 hours. On the next day, she felt much stronger, but later the weakness returned.

Over the entire course of her illness the patient has observed a decreased ability to learn and remember things. She has not been concerned or worried to any great degree about her difficulty.

Past History

Injuries and suggestive symptoms. At the age of 6, she was struck on the head with an icicle which caused no sequelae of importance. Her tonsils were removed in March 1926, under ether and she made a good recovery. She had diplopia in childhood, also chicken pox, measles and parotitis. She is still said to have tonsillitis occasionally. She had malarial fever in childhood and influenza in 1918. Her vision was good except for the fatigability of the ocular muscles. Five years previously she slept from 8 p. m. to 11 a. m. When 8-10 years of age, her mother said she had a habit of moving the mouth and lips.

Personal history. The patient was in the 8th grade in school when she was 14 years of age. She takes no tea or coffee, does not smoke or use drugs. She sleeps very well. Perhaps her sleeping is pathologically increased. Her appetite is good. She occasionally takes a little wine. Her bowels are constipated. Urination 8-10 times a day, none at night. Her periods are regular.

Family history. The patient's mother and father are living and well. She has two brothers and one sister, also living and well. The brother is nervous but the patient thinks this is from overwork. He is of the same general habitus as the patient and he used to have diplopia, but attributed this to eye muscle weakness.

Physical Examination

General appearance and cooperation. The patient cooperates perfectly, except for the fact that muscular fatigue prevents the sustained performance of some tests. She presents a somewhat peculiar appearance. The eyes are slightly prominent, the right

seems to show a very slight divergent strabismus. There is at times a definite widening of the palpebral fissures of both eyes and the appearance of a transient exophthalmos. She does not appear to be acutely or chronically ill, but there is an appearance of fatigue in the facial expression.

Abnormal attitudes and deformities. There are none other than the peculiarities mentioned above.

Gait. The gait is normal for the first few steps, but then becomes halting and that of a much fatigued individual. These peculiarities are brought out in other detailed tests for gait. The associated movements of the arms, head and trunk are present, but reduced in extent.

Coordination. The patient is right-handed.

Equilibratory. The patient stands well with the feet together, with the eyes open and closed, and also on one foot, but has some difficulty in maintaining her balance, not sufficient however, to be considered pathological.

Non-equilibratory. The finger-to-nose test is normally performed, as is also the finger-to-finger test. The finger-to-thumb test is well performed, but she tires very rapidly. The past pointing test is poorly done on account of the muscle disturbance, but she shows no constant lateral deviation. The tests of the lower extremities are well performed the first few times, but become imperfect if continued. Succession movements are poorly performed, chiefly on account of the recent weakness which affects the check element.

Skilled acts. She writes well; the speech is normal, except upon continued effort, when much more effort is required, and the voice becomes husky and the sounds somewhat indistinct.

Abnormal involuntary movements. None were noted, except for occasional protrusion and retraction movements of tongue.

Reflexes. The deep reflexes of the upper and lower extremities are all active and equal. The superficial reflexes of the abdomen and soles of the feet are absent, bilaterally.

Muscle strength. Muscle power throughout is poor except possibly in the forearms and the hands, where the grasp is well maintained for a short time, but becomes gradually weaker. In testing the forearm muscles, she flexes and extends her fingers 90 times in succession without any very marked fatigue. The effort, however, is not very active. The muscles of the shoulder girdle are quite weak. The same is true of the muscles of the hip and pelvic girdle,

while the extensors of the leg on the thigh are good for a brief period and then they readily fatigue.

Muscle status. The muscle tone is rather poor, the muscles throughout being rather soft and flabby.

Electrical reactions. The electrical reactions show the normal excitability to faradic current and the correct polarity in the galvanic reaction is present for all muscles tested. Faradic stimulation shows maintenance of tetanic contraction with application of the faradic current. After 40 consecutive stimulations, the left ulnar musculature shows some signs of fatigue. In none of the muscles is there the typical myasthenic reaction of Jolly.

Abnormal associated movements. None.
Meningeal irritation. Negative; no Kernig.

Sensory examination. The sensory examination is normal for all modalities.

Cranial Nerves

Olfactory nerve. The patient recognizes and names alcohol and vinegar readily.

Optic nerve. The visual acuity is normal in both eyes; the fields are complete and the fundi are normal, although the discs are somewhat oval vertically.

Oculomotor apparatus. The pupils are equal, measuring 5 mm. each in diameter, round and regular in shape, central in position. They react well to light, by direct stimulation and consensually, but the reaction to convergence and accommodation is only fair. In both eyes, there is a moderate exophthalmos, left greater than right. There is a slight right external strabismus on spontaneous direct gaze. The movements of the eyes are very much restricted.

The movement of the right eye to the right is very poor, and there is almost no upward or downward movement. The movement inward is good; this same thing is true of the left eye, but to a less extent. There is no definite nystagmus. The palpebral fissures are unequal, the left being greater than the right. At times there is a suggestion of ptosis.

Trigeminal nerve. Normal in the motor and sensory divisions: (see history of masticatory fatigue).

Facial nerve. The movement of the facial muscles in expression are rather reduced; there is no definite weakness in the volitional control except upon continued use of the facial muscles.

Acoustic nerve. Normal.

Glossopharyngeus and vagus nerves. Normal, except for the fatigability in the muscles of phonation and deglutition.

Spinal accessory nerve. Normal.

Hypoglossus nerves and tongue. The tongue protrudes in the midline, but the movement of the tongue becomes weakened upon continued exertion. There are occasional protrusion movements observed.

Systemic Examination

Tegumentary system. Normal.

Glandular status. There is apparent increase in the size of the thyroid. The tonsils have been removed and there is no lymphadenopathy.

Cardiovascular status. The pulse rate is quite variable, between 78 and 120 beats per minute. There is a considerable sinus arrhythmia which may account for the marked variations which are noted in the pulse rate; there are no murmurs heard and the heart is normal in size and outline. Blood pressure 110-68.

Respiratory system. The respiration rate is normal. The lungs seem normal to auscultation.

Gastrointestinal system. Normal.

Genitourinary system. Negative.

Skeletal system. Normal.

Mental status. History of difficulty in learning and retaining.

Laboratory Examinations

Blood Count

Hemoglobin	75%
Color index95
R.B.C.	3,900,000 per cubic mm.
W.B.C.	7,200
Neutrophils	70%
Small lymphs	28%
Large monos.	2%

Colloidal gold	Negative
Protein	28 mgs.

Urine

Color	Light amber
Reaction	Acid
Sp. gr.	1020
Albumin	0
Sugar	0
Indican	0
Pus cells	Few leucocytes
Epithelia	Squamous

Basal metabolic rate. Plus eight.

X-ray examinations. Examination of the thorax shows a slightly increased shadow in the superior mediastinum with a very slight deviation of the trachea to the left. The apices are clear. The increased shadow noted may be due to a persistent thymus gland, although the shadow is not characteristically shaped.

Examination of the skull shows nothing remarkable about the calvarium. The circulatory channels are normally visible as are also the convolutional digitations. A small deposit of calcium is noted in the pineal gland. The basal angle is normal. The sella is shallow, somewhat angular, but not wide open. Petroclinoid bridging is beginning to form on the left. The air cell development appears normal.

From the time of presentation until the date of death, the patient was under constant direction by letter or by visits to one of us (McKendree). There were definite variations in general muscular fatigue as well as in the fatigue of the masticatory, articulatory, and swallowing apparatus. Absolute rest, sunshine, and soft foods constituted the chief treatment, together with symptomatic medication, such as hormotone, thyroid substance, ovarian extract, and dextro-maltose. The menstrual periods were irregular, but otherwise normal. For the greater part of the time, the patient had to hold her lower jaw during the process of mastication. Fatigue of the vocal apparatus was always present after prolonged talking. Swallowing was difficult at times, with regurgitation of soft foods or liquids through the nose. The ocular muscles became rapidly fatigued while watching motion pictures. At times the general body musculature was as strong at the end of the day as upon awakening, but frequently throughout the period of observation, fatigue of the muscles of the upper and lower extremities appeared after relatively slight exertion.

Gradually the general and local myasthenic symptoms progressed until the patient became practically bed-ridden. Difficulty in breathing, chewing, swallowing, and inability to use the extremities for minor exertion made it necessary to advise hospitalization.

At this time, the general neurological examination was the same as that previously recorded, except for marked emaci-

ation, and more marked myasthenic reactions. Swallowing was no longer possible and articulation was practically abolished. General exhaustion and inanition were marked features.

The patient was accordingly admitted to the Neurological Institute on March 6, 1930, where she died five days later, from general exhaustion, cardiac and respiratory failure.

Pathology

At autopsy the body appeared wasted and thin. The subcutaneous fat was 8 mm. in thickness. The muscles of the trunk and extremities were reduced in size and pale. The temporal muscles were similarly changed. Grossly neither the serous cavities nor viscera showed any notable changes. The thymus was represented by a small amount of pink, soft, indefinitely lobulated tissue in the upper anterior mediastinum. It appeared infiltrated with fat.

Microscopic examination of the heart revealed occasional aggregations of lymphocytes in the subepicardial fat. The myocardial fibres were small, uniform in size and appearance, and many contained deposits of lipochrome pigment. There were a few lymphoid collections in the myocardium.

Specimens of the rectus abdominis, pectoralis major, intercostal and temporal muscles and of the diaphragm, appeared essentially normal. There was no apparent change in the muscle fibres, their sheaths, or in the interstitial connective tissue. No focal collections of lymphocytes were observed.

The internal secretory glands examined proved to be essentially normal histologically. There was a small zone of atrophy in the cortex of one adrenal, in which only the glomerular layer was preserved. Aside from this the adrenals were unchanged. Their cortices contained a moderate amount of lipid material. Several cortical adenomata were present. The medulla showed good chromaffin staining. The capillaries throughout were somewhat engorged. In the thyroid the acini were large, thin-walled, and well filled with colloid, some of which had escaped into the stroma in places. No lymphocytic infiltration was present. The left ovary contained a large hemorrhagic

cyst. A few Graefian follicles and small corpora albicantia were noted microscopically. No mature ova or corpora hemorrhagica could be seen. The vessels at the hila were congested. The islands of Langerhans were normal. Aside from congestion the pituitary was quite normal.

The thymus consisted of numerous small cellular lobules embedded in loose fibrous and fatty tissue. Few small Hassall's corpuscles were present and some seemed to be forming. One was fibrosed. In places there appeared to be epithelial hyperplasia, conspicuous large vesicular nuclei occurring in groups near the centers of lobules.

The microscopic examination of all the other viscera proved negative.

Grossly, the brain was essentially normal. The cerebral hemispheres were symmetrical. The gyri were well rounded and the sulci of normal width. The gyral pattern was of modern complexity. The pia-arachnoid was thin and translucent throughout and the leptomeningeal arteries and veins moderately well-filled. The cerebellum and stem showed no external abnormalities. The basal vessels were thin-walled and delicate. On section no microscopic abnormalities were found in the cerebrum, cerebellum or brain stem. Unfortunately there was no permission for removal of the spinal cord.

The brain had been fixed entire in 10 per cent formalin. On section alternate blocks of the brain stem and basal ganglia were washed and refixed in Zenker's solution and 95 per cent alcohol.

The alcohol fixed material was cut serially and stained with cresyl-violet. Sections of the Zenker fixed material were stained with hematoxylin-eosin, phosphotungstic acid-hematoxylin, and Mallory's connective tissue stains. (At the time the present study was begun only the blocks described above were available and many additional stains that were desired could not be made.)

Blocks from many portions of the cerebrum and of the cerebellum were taken and sections of each studied by the above methods.

Perivascular infiltration was a steadily recurrent, but not frequent feature of the findings in the brain stem and basal ganglia. It consisted of from two to eight rows of cells comprised of plasma cells, lymphocytes

and occasional monocytes (see Figs. 1, 2, 3). Its occurrence can be given most easily in tabular form:

Fig. 3 Perivascular Infiltration—Substantia Nigra Hematoxylin-Eosin Stain X 170

Fig. 4. Loss of Pigment and Chromatolysis in Ganglion Cells of Locus Caeruleus. Nissl Stain. X 170.

The ganglion cell changes observed in the Nissl stains were never very striking. Ghost and sclerotic cells were occasionally seen in the nuclei of the brain stem, but were not concentrated in any particular groups. Shrunken ganglion cells with little Nissl substance and pyknotic nuclei were also seen in these locations, but even less frequently. There was little evidence of degeneration in the substantia nigra or in the locus caeruleus. No evidence of abnormal lipid deposition in the neural elements in the brain stem was observed in the stains available. Occasional clusters of ganglion cells in the stem nuclei showed axonal chromatolysis. This was striking in a group of depigmented cells in the locus caeruleus (see Fig. 4).

In the basal ganglia ghost and shrunken nerve cells were moderately frequent in the globus pallidus and occasional among the large cells of the caudate nucleus and putamen. In the hypothalamus and cerebral cortex there were no nerve cell changes sufficiently notable to record.

There was a considerable amount of calcium-iron deposition in the globus pallidus, chiefly in its posterior two-thirds. Spherical, small, deeply staining masses of calcium and iron varying in size from fine granules to mulberry-like conglomerate masses 20-40 micra in diameter were found in perivascular spaces and in the walls, chiefly the adventitiae of blood vessels. They impregnated the walls of a great many capillaries and were occasionally present in perineuronal spaces.

Discussion

Oppenheim¹⁵ in describing myasthenia gravis referred to a group of borderline cases in which the syndrome was somewhat atypical. The present case undoubtedly belongs in that category and as has been pointed out there is evidence to suspect that it is a myasthenic syndrome following epidemic encephalitis. The patient had a mild attack of influenza in 1918 a few months before the onset of her symptoms. The eye signs, the protrusion and retraction movements of the tongue and the diurnal somnolence strengthen the likelihood of this diagnosis. As Grossman,⁸ Sarbo,¹⁸ Paulian,¹⁰ Wimmer-Vedmond,²³ and Guillain-Alajouanine-Kalt⁹ have pointed out the

myasthenic syndrome may be associated with epidemic encephalitis.

Many of the early investigators sought for the lesions of myasthenia gravis in the central nervous system with doubtful results. Oppenheim¹⁸ considered it a form of bulbar paralysis without anatomical findings. With Weigert's description (1901) of a case²¹ in which he found a thymoma and lymphomatous nodules in the muscles at autopsy, attention was focused on the thymus and the striated muscles. Persistence and hyperplasia of the thymus and neoplastic changes were described in cases of myasthenia frequently thereafter, but were certainly not constant, having been absent in Hutter's case and others. In our own instance there was some evidence of mild thymic hyperplasia, but it was insufficient in extent or intensity for any significance to be attached to it. Buzzard⁴ (1905) reported lymphorrhages in the muscles and this was often substantiated by other investigators. There are, however, a long series of cases in the literature such as those of Herzog and McAlpine,¹² in which no muscle changes were present. This was also true in the present instance. Querido¹⁷ found perivascular foci of lymphocytes, plasma cells and fibroblastic hyperplasia in striated muscles, liver, lungs, and kidneys. He suggested that the condition could be defined as a perivascularitis chronica proliferans and felt that the previously described findings in the muscles were the same thing. His hypothesis has received no further confirmation and his theory is unconvincing. The organs of internal secretion have been suspected from time to time of being the site of the essential pathology of myasthenia. The findings in these organs have not been convincing. The thyroid, parathyroids, and adrenals have been implicated, but the negative reports have seemed more impressive than the apparently positive ones. The minor focal cortical atrophy in one adrenal in our case is almost certainly unrelated to the myasthenic syndrome.

Attention has again been turned more recently to the nervous system in an attempt to discover the etiology of the disease. Barrada and Mott¹ (1923) reported a case in which they described generalized diminution of basophil sub-

stance throughout the central nervous system. It was most marked in the thalamus in which ganglion cell degeneration and neuronophagia were noted. Similar changes were less marked in the third and fourth cranial nerve nuclei. The other brain stem nuclei as well as the anterior horn cells of the spinal cord exhibited very little basophil changes, although here and there some cells were found with marked chromatolysis, eccentric nuclei, swollen and vacuolated cytoplasm and containing much lipid material. There was general congestion, but no hemorrhages or perivascular infiltration.

Biernmann and Scharapow³ described a case with degenerative changes in the ganglion cells of the sympathetic ganglia as well as in the adrenals. Van Bogaert²⁰ reported a rather atypical case which was considered by McAlpine,¹² however, to be very similar to his own case of myasthenia. There was subependymal perivascular infiltration in the floor of the fourth ventricle and to a slight degree in the midbrain. Chromatolysis was observed in the twelfth cranial nerve nucleus, Roller's nucleus, ventral nucleus of the seventh and dorsal nucleus of the tenth cranial nerves. The cord showed marked perivascular infiltration of the white matter by lymphocytes and plasma cells. The anterior horn cells were decreased in number and some exhibited chromatolysis.

McAlpine found a great deal of perivascular round cell infiltration chiefly in the white matter of the spinal cord in his case. The motor cells were normal throughout the cord. There was mucocytic degeneration throughout the central nervous system which was compared with a similar condition described in chronic epidemic encephalitis. The thymus was markedly hypertrophied.

Kononowa¹¹ described diffuse inflammatory and degenerative lesions giving the picture of an encephalomyeloneuritis. The peripheral nerves were partially degenerated.

Westphal and Meyer²² reported occasional mild perivascular lymphocytic and plasma cell infiltration in the cerebral pia and white matter, and in the brain stem. These were most marked in the hippocampal gyri. Rarely, focal areas of ganglion cell loss were found in the

cerebral cortex. Slight recent and old hemorrhages were also encountered in small numbers throughout the brain. The root of one of the fourth cranial nerves was infiltrated like the brain stem and in addition its septa contained numerous mast cells. The spinal cord and sympathetic nervous system was negative, as were the muscles. Westphal and Meyer were inclined to discount completely the significance of their findings. This point will be discussed further below.

Zajewloschin²⁴ described widespread inflammation of the nervous system most marked in the hypothalamus. This consisted of perivascular and diffuse lymphocytic infiltration and was accompanied by degenerative phenomena in the ganglion cells. The process was most intense in the cervical sympathetic ganglia. There was a thymic tumor and lymphoid collections in the muscles.

Tronconi¹⁰ found changes in the ganglion and glia cells of the nuclei of the vegetative and extrapyramidal centers, but denied their significance because of their presence in control material.

There were two cases that came to autopsy that were considered to be instances of the myasthenic syndrome following epidemic encephalitis. One was Grossman's⁸ second case. In this, perivascular lymphocytic infiltration and small perivascular hemorrhages were found in the brain stem, and were most marked in the midbrain. There was also evidence of a subacute process in the thickening of the blood vessel walls as well as in multiple areas of gliosis. Grönberg and Stenström⁷ reported the other case. In it they found perivascular round cell infiltration in the medulla with chromatolysis of the ganglion cells in the ninth nerve nuclei. There were perivascular hemorrhages and rare perivascular infiltration in the mammillary bodies. The spinal cord was normal.

In reviewing the pathological data relating to myasthenia gravis it becomes obvious that, as yet, there is no outstanding, constantly recurring constellation of lesions. The findings in the thymus and muscles are perhaps the most frequent, but they are often absent and their significance is obscure. It is clear, also, that recent studies of the nervous system in cases of myasthenia have given us no

definite clue as to the underlying pathology in the disease. As Westphal and Meyer pointed out, too much stress has been placed on minor ganglion cell changes in the brain stem. They point to the work of Gagel and Bodechtel⁶ who demonstrated similar changes in comparatively normal brain stems.

The perivascular round cell infiltration and small recent and old hemorrhages in their own and other cases were accepted by Westphal and Meyer²² as real lesions. The sparsity and distribution of these lesions led them to doubt their significance in causing the symptoms. It seemed more plausible to them that during periods of choking and dyspnoea, so common terminally in this disease, vascular spasm or faulty oxygenation mediated the perivascular changes. Even this cautious interpretation might be challenged for it is well-known that occasional perivascular lymphocytic infiltration may be encountered in so-called normal brains. In most of the cases cited in this report, including our own, perivascular infiltration although present has been relatively infrequent. Where diffuse lymphocytic infiltration is spoken of there may be some doubt as to the accuracy of the observation.

The variation in the distribution of the inflammatory lesions also induces doubt as to their relationship to the production of the symptoms. They include infiltration of the spinal cord alone or involvement of the brain stem, basal ganglia or hypothalamus with different zones of maximum involvement in these locations in each case. In our instance there is no possibility of correlation between the symptoms and signs and the inflammatory lesions. Nuclei and tracts in which one would expect to find changes are spared and others affected. We feel, therefore, with Westphal and Meyer that no typical pathological picture in the central nervous system has been established for myasthenia to date.

The relationship of the myasthenic syndrome to epidemic encephalitis, although probable, has no incontrovertible clinical evidence in its favor. McAlpine in reviewing the cases bearing on this point divides them roughly into two groups "(1) those in which the clinical picture of myasthenia is well represented, but in which the occurrence of a previous attack

of epidemic encephalitis is problematical; (2) those in which there is little doubt that the patient had an attack of epidemic encephalitis, but in which the condition that followed lacked several of the true myasthenic phenomena." He feels that the cases of Wimmer-Vedmond and Paulian fall into the first group and those of Sarbo, Grossman and Guillain, et al., into the second. As stated above there were clinical data to suggest that epidemic encephalitis was present in our case, but this was certainly not established beyond any possibility of doubt.

Pathological proof of the concurrence of myasthenia and epidemic encephalitis is lacking as yet. Grossman's second case in which there was an autopsy, developed brain stem symptoms late. The resemblance to myasthenia was slight. In Gronberg and Stenstrom's case the perivascular infiltration was practically confined to the medulla and some question might be raised as to the pathological diagnosis. McAlpine considered the possibility of epidemic encephalitis in his case, he pointed out the frequency of mucocytic degeneration, such as was present in his instance in that disease. The fact that inflammatory lesions were present chiefly in the spinal cord and were lacking in the other areas usually affected in epidemic encephalitis are arguments against this diagnosis. In the present case many of the zones ordinarily involved show changes. They are slight, however. It might be argued that after an illness last-

ing eleven years the inflammatory changes would be minimal. One would expect, however, to find more definite evidence of degeneration and gliosis.

The calcium-iron deposits in the globus pallidus in the present case must also be interpreted cautiously. As Jakob¹⁰ and others have pointed out, they occur in so-called normal brains and only when present in large amounts can they be considered pathological. Such mineral deposits in this region are not uncommon in chronic epidemic encephalitis, however. We feel that they are sufficiently marked in this case to be considered pathological. They are coupled with cell changes and occasional perivascular infiltration.

Conclusions

The changes found in the central nervous system in our case, on the whole, impress us as pathological but quite moderate. Their relationship to the myasthenic syndrome is far from certain. In view of the clinical facts that point to epidemic encephalitis, the possibility that the anatomic findings are an expression of that disease cannot be ruled out. It is obvious, however, that this cannot be considered an anatomically proved case of myasthenic syndrome following epidemic encephalitis.

We join Westphal and Meyer in urging the greatest caution in the estimation of the significance of changes in the nervous system in cases of myasthenia gravis.

CASE REPORT

DISSECTING ANEURYSM OF THE AORTA

Diagnosis and Operative Relief of Acute Arterial Obstruction Due to This Cause

DAVID GURIN, M.D., *Great Neck*
JAMES W. BULMER, M.D., *Glen Cove*
and
RICHARD DERBY, M.D., *Oyster Bay*

According to the recent reports of Weiss¹ and of White, Badger and Castleman,² the frequency of dissecting aneurysm of the aorta is about 1 in 350 necropsies of adults. In the course of any general medical or surgical experience, the condition may therefore be expected to present itself at some time. Yet, of the ten cases reported by Weiss, only one had been correctly diagnosed antemortem and, of eighteen dissecting aneurysms found in 7000 necropsies at the Massachusetts General Hospital, none had been identified before death.² Shennan³ has analyzed 300 cases reported in the literature. He personally saw at autopsy sixteen dissecting aneurysms, none of them recognized before death. Kellogg and Heald⁴ made the correct diagnosis during life and found reports of thirteen other such cases. To these we add one in which surgery relieved arterial obstruction of an extremity.

Report of Case

At about 9:30 p. m., April 14th, 1935, J. R., a 43 year old negro laborer whose previous history was negative except for nocturia 10x of a month's duration, developed sharp epigastric pain. One of us (D.G.) saw him about an hour after on-

set of his symptoms. The pain was then excruciating in severity. It had traveled downward and to the right thigh. He complained of coldness and diminution of power in the extremity. These complaints were confirmed on examination. There was blanching of the nail beds of the right toes. No pulsation could be felt in the dorsalis pedis, posterior tibial, or popliteal arteries. A weak impulse was palpable in the right femoral artery. There was no oscillation of the mercury column when a sphygmomanometer cuff was applied to the right calf. On the left pulsation was forceful throughout. Pulsation of the aorta was felt through the abdominal wall.

In general examination the heart was found enlarged to the left, reaching nearly to the anterior axillary line. Heart sounds were loud and regular, rate 90. There was a harsh systolic murmur, most intense in the aortic area. The blood pressure was 280/150. Peripheral vessels and those of the retina showed evidence of this high tension. Temperature was 99°F. A urine specimen had a specific gravity of 1.020, with albumin 1 plus, sugar none, and a few w.b.c., r.b.c. and finely granular casts.

A diagnosis of aneurysm dissecting the

aorta and occluding the right external iliac and femoral arteries was made. It was felt that in spite of the marked hypertension and cardiovascular and renal damage, surgery might prevent an otherwise inevitable gangrene of the extremity.

Operation

Two and a half hours after the onset of his symptoms the right femoral artery was exposed under local anesthesia (by JWB and RD). At the beginning of the operation a faint pulsation could be felt in the femoral artery. On exposing the vessel no pulsation was visible or palpable. Its wall was intact, and no mass could be felt in the lumen. Aspiration with a fine needle revealed bright blood under markedly diminished pressure. The wound was closed and under nitrous-oxide oxygen and ether anesthesia the abdomen was opened. The right external iliac artery when isolated three inches above Poupart's ligament was found to have an infiltration of dark blood in its lateral third, extending as far as could be seen in both directions. An impact was transmitted along the artery from above with each heart beat, but there was no expansible pulsation in any part of the vessel. Rubber prided clamps were placed on the artery above and below to prevent any influx of blood. Then a longitudinal one inch incision was made into the anterior surface, which appeared unaffected by the hemorrhagic extravasation. Upon entering the vessel an atheromatous mass was encountered completely plugging the lumen which had been narrowed by the dissecting hemorrhage. The intima and media opposite the atheroma were incised from within the vessel. A small curved Kelly clamp was inserted through this incision into a space between the media and adventitia. From this came a steady flow of dark unclotted blood. With the escape of this blood the obstruction was relieved, and when the proximal clamp was momentarily released, there occurred a spurt of bright arterial blood from the incision. The incision into the vessel was closed with interrupted suture of greased silk. When the clamps were removed an expansile pulsation was visible throughout the external iliac artery.

Postoperative Course

On his return from the operating room pulsation was felt in the right dorsalis pedis artery and the limb was warm. After recovering consciousness he developed a cough productive of bloody purulent sputum. X-ray taken 36 hours after admission showed a patchy pneumonia involving the right lower lobe. The urea nitrogen reached 66.7 mg and the creatinine 4 mgs per 100 cc on the fifth day after operation. The temperature rose to 103.5° and he expired on the sixth day. Circulation in the right lower extremity remained unimpaired until his death. The blood Wasserman was reported negative. No near relative was available to give the necessary permission for an autopsy.

Discussion

Dissecting aneurysm of the aorta is a hemorrhagic extravasation which begins most often in the ascending portion of the arch of the aorta and spreads through the media, usually adjacent to the adventitia. In its course the extravasation may cause compression of any of the branches of the aorta, including the coronary arteries. In the majority of cases severe hypertension with systolic pressure of over 200 has been pre-existent. Dissecting aneurysm is not the common terminus for severe hypertension, suggesting that the aorta in these cases must be more fragile than usual. Obliterating sclerosis of the vasa vasorum with consequent degeneration of the media has been frequently described.¹ The findings are those of malignant hypertension, with the vasa vasorum the site of the most advanced arteriolar lesions. Syphilis is rarely a cause of this condition because the layers of the luetic aneurysm fuse, and rupture is usually not accompanied by splitting. Likewise accidental trauma may cause rupture but rarely dissection. Status lymphaticus and coarctation of the aorta have been described as causing rupture with a certain amount of dissection.

According to Kellogg and Heald, sixty-five per cent of cases of dissecting aneurysm die immediately from complete rupture of the aneurysm. Rupture is most frequently into the pericardium, pleural cavities or mediastinum. Another fifteen per cent die in a few days (the patient

they reported died of gangrene of the lower extremities). The remainder have a good chance of recovery but may re-rupture.

Healing occurs by (a) absorption of blood and eventual fusion together of the layers of the media or (b) by establishment of a new arterial channel along the course of the dissection, lined by endothelium and communicating above and below with the lumen of the aorta or one of its branches.³ The operative procedure used in the case which is being reported would facilitate healing by either method as well as relieve the immediate obstruction.

The diagnosis of dissecting aneurysm⁶ should be *suspected* when an individual,

usually (75%) male, usually with history or evidence of severe hypertension, suddenly develops pain at the level of the precordium without evidence of acute myocardial damage by E K G, fall in blood pressure or marked rise in pulse. Often the pain in these cases is more severe over the thoracic spine or in the epigastrium than under the sternum. The diagnosis should be made when following the above, signs of acute arterial blockage or internal hemorrhage develop. Valvular heart disease, auricular fibrillation or other source of embolism can ordinarily be ruled out. Infection, cachexia or mechanical pressure causing thrombosis are also absent in dissecting aneurysm.

AROUND THE STATE

"FORTY-THREE out of every 100,000 persons in Brooklyn died of pulmonary tuberculosis in 1934 as compared with 173 out of every 100,000 20 years ago," Dr. Thomas A. McGoldrick told 150 members of the Medical Society of the County of Kings at the Society Center, on Nov. 1.

THE MONTHLY MEETING of the Woman's Auxiliary to the Medical Society of the County of Kings was held at the society building, on Nov. 12.

Dr. W. W. Bauer of Chicago, director of the Bureau of Health and Public Instruction of the American Medical Association, spoke on "Centuries of Progress in Medicine." Following the meeting there was a tea under the supervision of Mrs. William Lippold, chairman of hospitality.

THE WESTCHESTER COUNTY Medical Society has adopted resolutions recommending that maternal health centers being established in the county "should be brought under the responsibility and control of the

medical profession, preferably through the recognized community hospitals in their Departments of Gynecology."

THE CAMPAIGN against pneumonia was discussed at the meeting of the Cortland County Medical Society at the County Hospital in Cortland on October 18. Speakers were Dr. Charles D. Post, of Syracuse University, and Dr. M. R. French, county health officer. Twenty-five physicians were present.

"EMPYEMA" was the subject of Dr. P. N. Coryllos, of the Cornell Medical School, at the meeting of the Broome County Medical Society at the Binghamton Club on Nov. 5.

DR. HUGH YOUNG of Baltimore, an authority on cancer of the prostate and bladder, addressed the Glens Falls Academy of Medicine on Oct. 25, urging approximately 100 physicians and surgeons of Glens Falls and vicinity to stimulate yearly examinations to help curb the disease.

THE LIFE-SPAN OF THE DIABETIC PATIENT

Report of 1,500 Cases, 13 years after the Discovery of Insulin

JOSEPH HAJEK, M.D., *New York City*

In 1922 Banting and Best introduced insulin in the treatment of diabetes mellitus. In that year the supply of insulin was limited but beginning with 1923 it became sufficient, so that up through 1934 there has elapsed a period of 12 years during which insulin has been universally in use. Within these 12 years we have treated 1,387 patients in the wards of St. Luke's Hospital. Prior to the discovery of insulin, during the period 1920-21, we had the opportunity of observing 113 cases, so that our entire series comprises 1,500 patients. This group is analysed with reference to general mortality, deaths due to coma, surgery, arteriosclerosis, infection, neoplasm, age, sex, and the average duration of life.

These 1,500 cases therefore represent the pre-insulin period 1920-21 and the post-insulin period 1923-1934, the year 1922 being intentionally omitted because the supply of insulin was small. Our pre-insulin series is composed of 113 cases and the post-insulin period is represented by 1,387 cases. For the sake of comparison, the post-insulin period is divided into the early post-insulin period 1923-1930 comprising 872 cases, and the late post-insulin period 1931-1934, when 515 patients were seen. Thus we have for comparative study three groups of patients as follows: Group I, pre-insulin period, 113 cases; Group II, early post-insulin period, 872 cases; and Group III, late post-insulin period, 515 patients. These three groups are shown as follows:

Group	Period	Number of cases
Group I	Pre-insulin years 1920-21.....	113
Group II	Early post-insulin years 1923-30....	872
Group III	Late post-insulin years 1931-34....	515
Total.....		1,500

General mortality. Since the introduction of insulin the general mortality has been greatly reduced. This reduction was not so apparent during the early post-insulin period, but it has been marked in the late post-insulin years. It was

shown in a previous paper* that during the early post-insulin period the decrease in general mortality at St. Luke's Hospital was entirely accounted for by the diminution in deaths due to coma. The late post-insulin period indicates a further striking decrease in general mortality and this is due to the elimination of deaths from coma, and a diminution in mortality from infection. The general mortality is illustrated as follows:

Group	Period	No. of cases	No. of deaths	% mortality
Group I	Pre-insulin period 1920-21	113	22	19%
Group II	Early post-insulin period 1923-30	872	101	11.6%
Group III	Late post-insulin period 1931-34	515	38	7.4%

Mortality due to coma. During the early post-insulin period (1923-30) coma was seen four times less frequently than in the pre-Banting era (1920-21). In the late post-insulin years (1931-34) it was eight times less frequent. The reason for this is that we had learned how to treat coma in the first instance, and made an attempt at its prevention in the second. As a result, the mortality from this cause decreased from 54 per cent in the pre-insulin years to 5 per cent during the early post-insulin period. There were no deaths in the late post-insulin years. This striking diminution in mortality is entirely accounted for by the use of insulin, the widespread knowledge of the disease, education of the patient, and the early diagnosis and treatment of ketosis. Since our diabetic patients are saved from coma, it would appear that their life-span has been increased. The average age at death in the pre-insulin years was 55 years and remained the same during the early post-insulin period. It is 59.8 years during the late post-insulin years, an increase of

* Hajek, Joseph: N. Y. STATE JOURNAL OF MEDICINE, 33:802, 1933.

4.8 years. The mortality due to coma is illustrated as follows:

Group	Period	No. of cases	No. of deaths	% 1 coma
Group I	Pre-insulin period 1920-21	113	22	54%
Group II	Early post-insulin period 1923-30	872	101	5%
Group III	Late post-insulin period 1931-34	515	38	0%

Surgical Mortality. Before the discovery of insulin the surgical diabetic patient was as hopeless as the medical patient was in coma, and the mortality was correspondingly high. Since Banting's great discovery the surgical patient has become a good risk. These patients have been taught personal hygiene, care of their extremities, and the value of early treatment. During the pre-insulin period only 1 out of every 10 diabetics was operated on, and even then the mortality was high; in the early post-insulin period, however, 3 out of every 10, and in the late post-insulin period 4 out of 10 were operated on, and there was marked reduction in deaths. The decrease in surgical mortality at St. Luke's Hospital is shown as follows:

Group	Period	No. of cases	% mortality
Group I	Pre-insulin period 1920-21	13	33%
Group II	Early post-insulin period 1923-30	257	16.3%
Group III	Late post-insulin period 1931-34	195	8.7%

Mortality due to arteriosclerosis. It has been shown that mortality due to coma has greatly decreased, and indeed during the late post-insulin years we had no deaths from this cause at St. Luke's Hospital. What happens to the patients who are saved from coma? To be sure, they go on living, although many develop arteriosclerosis or die of infection or neo-

plasm. But lately they have been taught how to avoid infection; therefore many patients of the type which during the early post-insulin period died of infection are now spared, but become stricken either with arteriosclerosis or neoplasm. Thus the three principal causes of death of the diabetic in the order of their importance are arteriosclerosis, infection, and neoplasm. Since our diabetic patients can avoid coma, thanks to Banting, and more and more of them prevent infection, it would seem that they have increased their life-span. The average age of the diabetic patient at death, during the late post-insulin period, was 59.8 years, or 4.8 years more than during the pre-insulin period and the early post-insulin years. Every diabetic patient saved from coma is a potential case of arteriosclerosis, but to develop it he has to live longer than he did before the discovery of insulin. This accounts for the great increase in mortality due to arteriosclerosis and for the increase in his life-span. The great increase in mortality from arteriosclerosis is illustrated as follows:

Group	Period	No. of cases	No. died	% arteriosclerosis
Group I	Pre-insulin years 1920-21	113	22	28%
Group II	Early post-insulin years 1923-30	872	101	50%
Group III	Late post-insulin years 1931-34	515	38	63%

Mortality due to infection. Mortality from infection was lowest during the pre-insulin period but showed a marked rise during the early post-insulin period. In the late post-insulin period the death rate due to infection diminished, and this decrease is largely due to the education of the patients in their personal hygiene, and

GRAPH—REDISTRIBUTION OF DEATHS

the use of insulin. The mortality from infection is shown as follows:

Group	Period	No. of cases	No. died	% infection
Group I	Pre-insulin years 1920-21	113	22	18%
Group II	Early post-insulin years 1923-30	872	101	36%
Group III	Late post-insulin years 1931-34	515	38	21%

Mortality due to neoplasm. Since our diabetic patients live longer, more of them die of neoplasm, and this increase in mortality is shown as follows:

Group	Period	No. of cases	No. died	% Neoplasm
Group I	Pre-insulin years 1920-21	113	22	0%
Group II	Early post-insulin years 1923-30	872	101	9%
Group III	Late post-insulin years 1931-34	515	38	16%

To illustrate the striking redistribution of deaths due to arteriosclerosis, infection, coma, and neoplasm during the past 12 years we have prepared the accompanying graph.

Age. The redistribution of mortality in diabetes is due to several factors: (1) introduction of insulin which resulted in the saving of thousands of diabetic patients, (2) widespread knowledge of the disease by the profession and the laity, (3) improved methods in laboratory diagnosis, (4) education of the patient, (5) cooperation of the hospital with the diabetic clinic, (6) early diagnosis of ketosis, (7) personal hygiene, and (8) complete follow-up. The combination of these factors resulted in marked diminution in general mortality, deaths due to coma, and to infection, in consequence, the average age at death has risen from 55 in the pre-insulin and early post-insulin periods to 59.8 during the late post-insulin period. This is illustrated as follows:

Group	Period	No. of cases	No. died	Average age at death
Group I	Pre-insulin years 1920-21	113	22	55 years
Group II	Early post-insulin years 1923-30	872	101	55 years
Group III	Late post-insulin years 1931-34	515	38	59.8 years

Sex. The sex ratio has undergone a rapid change. In 1916 Osler gave the ratio of male to female as 3.2. Joslin in 1931 states that the proportions of males had decreased to 44 per cent in contrast to 47 per cent in 1921 and 55 per cent a decade before.

In our series at St. Luke's Hospital the proportion of males has increased from 44 per cent in 1920 to 49 per cent during the early post-insulin period and has diminished to 40 per cent in the late post-insulin years, shown in the following:

Group	Period	No. of cases	% of males
Group I	Pre-insulin years 1920-21	113	44
Group II	Early post-insulin years 1923-30	872	49
Group III	Late post-insulin years 1931-34	515	40

Summary

1,500 cases of diabetes mellitus are presented with reference to general mortality, deaths due to coma, surgery, arteriosclerosis, infection, neoplasm, age, sex, and the average age at death.

1. The general mortality has decreased from 19 per cent in the pre-insulin period to 11.6 per cent and 7.4 per cent during the early and late post-insulin years.

2. Deaths due to coma diminished from 54 per cent during the pre-insulin years 1920-21 to 5 per cent in the early post-insulin years 1923-30. There was no mortality from coma at St. Luke's Hospital in the late post-insulin years 1931-34.

3. Surgical mortality decreased from 33 per cent in group I to 16.3 per cent in group II and 8.7 per cent in group III.

4. There is marked increase in deaths from arteriosclerosis. In group I 28 per cent of the deaths were due to this cause, in group II 50 per cent, and in group III 63 per cent.

5. Mortality due to infection has decreased from 36 per cent in the early post-insulin period to 21 per cent in the late post-insulin period.

6. Neoplasm as a cause of death is on the increase during the late post-insulin period. While there was no mortality from neoplasm during the pre-insulin period it rose to 16 per cent in the late post-insulin period.

7. Forty per cent of the diabetics were males in group III, forty-nine per cent in group II, and forty-four per cent in group I.

8. The average life span of the diabetic at St. Luke's Hospital has increased from 55 to 59.8 years.

9. Thirteen years after Banting's discovery of insulin the adult diabetic is able not only to live but also to die like a person without this disease.

555 PARK AVENUE

CHOLECYSTECTOMY IN TYPHOID CARRIERS

Report of Five Cases

EILIF CARL HANSEN, M.D., *New York City*
Assistant Surgeon, New York Post-Graduate Hospital

Typhoid carriers are roughly classified as feces carriers and urine carriers. Urine carriers are rare. The feces carrier is the common variety. Garbat¹ in 1922, as a result of a study of 164 cases of typhoid fever, demonstrated that there are three distinct types of feces carriers according to the nidus of infection: the liver carrier, the gallbladder carrier, and the intestinal carrier. In the first two the bacilli enter the intestine with the bile. In the intestinal type the bile passages are free from infection. The gallbladder carrier is by far the commonest of the three types of feces carriers. Garbat also pointed out that duodenal intubation culture was a more reliable method of determining the bile carrier state than stool culture. He showed that stool culture failed to detect the bacilli in fifteen per cent of carriers.

In 1933 there were 662 carriers on record in New York State.² Of these 340 were in New York City. During the same year thirty-eight new carriers were added to the register. The control of the typhoid carrier, once he has been detected, becomes a serious problem. In addition to his being a constant source of danger to the health of the community, he often becomes a financial burden to the state.

Although as early as 1907 Dehler³ cured the carrier state in one case by cholecystectomy, this method of treatment has not been used extensively, judging from the number of cases reported in the literature. The largest reported series of operations on the gallbladder for cure of the typhoidal carrier state are those of Bergglas⁴ of Germany who reported seventy-four cases in 1929, and Senftner⁵ and Coughlin who collected sixty-eight such cases in upstate New York and reported them in 1933. The Haalands⁶ of Norway reported fourteen cases in 1927, and Whipple⁷ fourteen cases from the Presbyterian Hospital in 1929. In 1933 Bigelow⁸ and Anderson of Boston reported twelve cases.

Our series consists of five cases which came to operation out of a series of fifteen cases investigated from the carrier standpoint in our clinic for the Study of Diseases of the Liver and Biliary Tract. Prior to operation bile and stool cultures were obtained in each case. At operation cultures were made of the fluid contents of the gallbladder and of the wall of the gallbladder. Gallstones and cystic duct lymph nodes were cultured when present. Following operation cultures of bile and stool specimens were made during the patient's stay in the hospital and also after discharge at follow-up visits.

All five cases of our series were known typhoid carriers for periods varying from three months to three years. Bile and stool cultures were positive in each case prior to operation. One patient was operated on three months after typhoid fever for which she had been treated in the medical ward. The remaining four patients were ambulatory carriers registered with the State Department of Health. Three of our patients were males and two females. Two out of the five carriers (40 per cent) denied having had typhoid fever, but in both cases a history of exposure to typhoid fever was obtained. The operation performed in each case was cholecystectomy. At operation gallstones were found in four out of five of the cases. *B. typhosus* was cultured from the fluid contents of the gallbladder and wall of the gallbladder in every case, and from the gallstones, and cystic duct lymph node in two cases.

All five patients recovered, and all were cured of the carrier state, as shown by repeatedly negative bile and stool cultures following discharge from hospital. Bigelow and Anderson also report 100 per cent cures in their series of twelve cases following cholecystectomy. The Haalands report 84.5 per cent cures. They report thirteen cholecystectomies and one cholecystostomy. One of the cholecystectomies

Read before the New York Surgical Society at the New York
Post-Graduate Hospital, March 27, 1935

died six days after operation. Of the thirteen survivors, one remains a liver carrier, one a liver and urinary carrier. Whipple reports 83.3 per cent cures. Two of his series of fourteen cases had a cholecystostomy done. One remained a carrier. Of the twelve cholecystectomized patients two died, but both these patients were deeply jaundiced and were operated upon for long standing gallstone disease with cholangitis. "Of the ten surviving cholecystectomies, all were cured of the carrier state except one patient who is still a carrier nine months after his operation. His duodenal bile still shows typhoid bacilli and he has to be classed as a liver carrier."

In the series of Bergglas 73 per cent were reported cured. Senftner and Coughlin in a very careful analysis of their series of sixty-eight operated cases, reported only 68 per cent cures. A recent personal communication⁹ from these authors furnishes a most interesting explanation of how they interpreted their results and emphasizes the importance of careful preoperative, operative, postoperative, and follow-up data in these cases:

Our percentage of cures was based on the forty-one carriers (out of a total series of sixty-eight operated cases) from whom *B. typhosus* was isolated from the bile prior to or from the gallbladder at the time of operation. Of these, seventeen were cured on the basis of three negative duodenal and eight negative fecal specimens.

Inasmuch as we could not be certain of cure in those who did not have duodenal specimens, ten of the forty-one who had four negative fecal specimens but no duodenal specimens were excluded in making the percentages; two who had neither fecal nor duodenal specimens subsequent to operation were naturally excluded. Of the forty-one, four died. The figure 68 per cent was based on the twenty-five carriers from whom sufficient duodenal and fecal specimens were submitted and who recovered from the operation, i.e., seventeen of twenty-five. The figure fifty-nine was based on the same group plus the four who died, i.e., seventeen of twenty-nine.

It is unfortunate that out of the sixty-eight carriers who had had gallbladder surgery at the time our paper was prepared, the work-up was sufficiently complete for a study of the results in less than half.

I wish to cite a typical case. The patient is a groceryman, 42 years of age. He was

referred to us by the New York State Department of Health as a typhoid carrier. He was discovered to be a carrier six weeks prior to admission. He denied having had typhoid fever, but gave a history of exposure to his son, who had had typhoid fever two months previously. His history was otherwise essentially negative except for a previous appendectomy. His physical findings showed nothing abnormal except for the presence of *B. typhosus* in cultures of stool and bile. The cholecystogram revealed a normally functioning gallbladder without evidence of calculi. Cholecystectomy was performed by Dr. Charles Gordon Heyd on January 23 of this year. At operation the gallbladder appeared unusually large, intrahepatic, intensely red with marked telangiectasis over its fundus. There were chronic inflammatory adhesions to the hepatic flexure and gastrohepatic omentum. The gallbladder contained two calculi each about one centimeter in diameter. Cultures of the wall of the gallbladder, of the contents of the gallbladder, and of the gallstone all yielded *B. typhosus*. In this case specific bacteriophage was administered, intravenously the day before operation and the morning of operation. At operation the phage was recovered in fair potency from contents of the gallbladder and in still greater potency from the wall of the gallbladder. Convalescence was uneventful. A culture of the stool fourteen days after operation was negative for *B. typhosus*. At a follow-up visit four weeks after operation, cultures of bile obtained by biliary drainage as well as cultures of the stool were reported negative for this organism. This patient's nidus of infection evidently was his gallbladder, since following its removal he has been cured of his carrier state.*

Similarly, the nidus of infection in the remaining four of our cholecystectomized patients must have been the gallbladder, since in each case removal of the gallbladder was followed by cure of the carrier state.

Seven additional patients who had had cholecystectomy elsewhere for cure of the

* Since the original report was made, this patient has been found to be qualified for release from Department of Health supervision, having had 3 negative duodenal and 8 negative stool cultures.

carrier state were recently studied at our clinic by nonsurgical biliary drainage culture to determine whether the operation resulted in the desired effect. In every case the bile cultures were reported negative for *B. typhosus*.

In conclusion we may state that our findings substantiate those of previous investigators, namely, that cholecystectomy in bile typhoid carriers is curative when the gallbladder is the nidus of in-

fection. We urge that removal of the gallbladder for cure of this unfortunate condition be encouraged.

Acknowledgment

The author wishes to express his thanks to Dr. Charles Gordon Heyd, Dr. Edward W. Peterson, and Dr. R. Franklin Carter who have provided the material used in this paper.

CASE REPORT

GONOCOCCEMIA WITH COMPLETE RECOVERY

S. H. KRITZALIS, M.D., *New York City*

Infections such as these rarely happen in private practice and of course escape compilation in the statistics either of private hospitals or of other allied institutions. From time to time one reads reports of cases similar to this, with recovery. Their authors state the extreme difficulties of obtaining cultures of the gonococci and many times, therefore, a true clinical diagnosis is a hardship, and everyone can realize this handicap which obscures the prognosis of such severe infections of so-called gonorrheal sepsis or gonococcemia.

The case here described dates back almost two years. The reason for this delay in reporting is one of professional satisfaction, which allowed for a longer period of careful observation to be assured of a complete recovery of the local infections without complications or residual lesions. The author carefully investigated the literature relative to this subject and found an excellent bibliography in the recently reported case of Dr. William Filler.¹

In all the reported gonococcemias it appears that blood transfusions have been

resorted to in only two cases, Garlock² and Rubenstone.³ Garlock used 5 transfusions with no apparent improvement until he resorted to surgical intervention. Rubenstone gave one transfusion of 250 c.c. with a resultant improvement, but did not follow up. The present report will illustrate the value of blood transfusion, in this form of gonorrheal bacteriemia, or gonococcemia.

Report of the Case

The patient, J. C., a single male 38 years old, was seen in consultation December 2, 1931. He has been under treatment for an acute gonorrheal urethritis for a month or so. A few days before consultation he developed a high fever, preceded by chills. He had in addition the symptom complex of muscular pains, general weakness, headache, and slight urethral discharge.

According to the attending physician the patient was on a diet for his gonorrheal infection, and was being treated for a cold. The data of his gonorrheal infection and the recent symptomatology of the supposed cold were noted. Careful examination revealed involvement of four joints: right elbow, left knee, left wrist, and left thumb. There were also a few characteristic red

maculopapular lesions in the skin of the chest, extreme tenderness of the plantar aspects of both feet, and general pallor. The prostate gland was found to be enlarged and the slight urethral discharge was positive for a gram negative intracellular diplococcus. There were no signs of any respiratory system pathology, except for a slight injection of the tonsils and nasopharynx, which certainly could not account for such a severe illness. The spleen was just palpable and examination of the heart elicited no definite signs of any organic lesion other than a slight systolic murmur.

Realizing the serious condition of the patient and suspecting a blood stream infection, the author suggested removal to a hospital for therapy and closer observation.

On the eighth day of his illness he was hospitalized. The following day the fever reached 105.3° F. in the afternoon and the next morning 98° F. The same septic tem-

perature continued daily until the twelfth day. Because protein therapy and salicylates failed, because of fear of losing time even in the attempt to utilize any other palliative treatment, because of the seriousness of the case, and also because the patient was sinking rapidly, the author suggested a consultation with specific reference to a transfusion, with the thought that this would be the only hope of salvation.

On the twelfth day of illness a consultant agreed that the case was one of gonococemia, though not a single positive culture could be obtained, even after repeated trials. The next day at 6 00 p.m. when the temperature was 99.5° F the transfusion of 250 c.c. of whole blood was effected. From that date until the nineteenth day of illness the temperature was almost normal, the patient felt fine, and the only discomfort was the profuse perspiration. The patient slept well during all that period, the appetite

CHART—TEMPERATURES OF THE PATIENT BEFORE AND DURING HOSPITALIZATION,
DATES OF FIRST AND SECOND TRANSFUSION AND DATE OF HIS DISCHARGE.

was improved very much, and the swelling of the said joints had receded.

On the nineteenth day the temperature started to rise again, being 100° F. that afternoon, and on next morning 100.3° F. Fearing a repetition of the previous syndrome, the author thought that another transfusion probably would be salutary. On the twenty-first day a transfusion of 300 c.c. was given and since that time, until the date of discharge, as can be seen in the chart, the temperature, pulse and heart were normal. During his stay in the hospital the laboratory reported repeatedly negative blood cultures, negative Wassermann, 100 pus cells per high power field in repeated urine examinations, negative gonococcus complement fixation test, but positive smears from the slight urethral discharge mentioned above, and the following blood count on the date of admission: hemoglobin 90 per cent, 4,600,000 R.B.C., 20,800, W.B.C. of which latter there were 82 per cent neutrophils, 16 per cent small lymphocytes, and 2 per cent large lymphocytes.

After a week or so a little purulent urethral discharge appeared with a positive smear for gonococci. He received routine office treatment for about 7 weeks. When prostatic smears became repeatedly negative, the patient was discharged, with the suggestion that he appear once every 3 months for observation. After a lapse of time this patient seems to enjoy life in complete and perfect health.

Comment

Many gonorrheal arthritis cases are undoubtedly undiagnosed mild gonococcemias. Some clinicians believe that gonococcemias are much more frequent than have been demonstrated in the laboratories and therefore content that the percentage of recoveries is greater than formerly thought. Many observers recommend surgical intervention or other treatment because the few transfusions recorded in the literature of such cases seemed unsuccessful. However, this case demonstrates clearly the value of blood transfusion in gonococcemias, and the author strongly recommends early use of blood transfusion in all cases in order to shorten the dangerous stage of the infection and to give ample opportunity to treat the focus subsequent to recovery from the gonococcemia.

GOVERNMENT MEDICAL POSITIONS OPEN

The U. S. Civil Service Commission announces open competitive examinations for two Children's Bureau positions and for Principal Medical Officer of the Indian Service at Large.

Applications for the positions of director, Division of Maternal and Child Health, \$6,500 a year, and director, Crippled Children's Division, \$6,500 a year, Children's Bureau, Department of Labor, must be on file with the U. S. Civil Service Commission, Washington, D. C., not later than December 9, 1935. The salaries are subject to a reduction of 3½ per cent toward a retirement annuity. Applicants must have been graduated from a medical school of recognized standing with a degree of M. D. and, in addition, must have had certain specified experience.

Applications for the position of principal medical officer, Indian Service at Large, must be on file with the U. S. Civil Service Commission, Washington, D. C., not later

than December 9, 1935. The entrance salary is \$5,600 a year, subject to a deduction of 3½ per cent toward a retirement annuity.

Applicants must have been graduated from a recognized medical school with a degree of M. D. and must be licensed to practice medicine in a State or Territory, or in the District of Columbia. They must have had not less than 5 years' experience in the vaccination of newborn infants with bacillin Calmette-Guerin vaccine according to the method of Calmette, and not less than 3 years' experience in city, State, or Federal public health laboratories with work in tuberculosis. The two types of experience mentioned may run concurrently.

Full information may be obtained from the Secretary of the United States Civil Service Board of Examiners at the post office or customhouse in any city which has a post office of the first or the second class, or from the United States Civil Service Commission, Washington, D. C.

THE BORDERLINE CONDITIONS BETWEEN MEDICINE AND SURGERY

EDWARD L. YOUNG, JR., M.D., F.A.C.S., *Boston, Mass*

In order properly to discuss the subject which we have undertaken to bring before you, it is necessary that we get clearly before us the exact place in the general scheme of medicine that is held by what we call the medical man or the general practitioner, and the surgeon, and I think a short review of the development of the surgeon may help us to understand a little better his place in the picture.

A great many years ago, or to put it in the words of Kipling, "In the high and far off times when the world was very young," there was no true knowledge of medicine and those who attempted in any way to influence disease belonged largely to the priesthood, and aside from a few empiric remedies, relied mostly on magic and incantations. As a separate group of men gradually evolved who took unto themselves the care of the human body in disease, their essential ignorance still necessitated much of the old mysticism and magic. All of the trappings of the profession which would accentuate the awesomeness in the mind of the patient were very much to the front both in clothing and in other outward evidences of their position, and also in the mysterious manners which they affected. These were really necessary to take the place of or rather, to cover up their lack of knowledge. So great was the need of sustaining their position that any descent to the lowly level of actually doing something was undreamed of. It was beneath their dignity, for instance, to have anything to do directly with blood letting in any form so it came about that barbers were entrusted with all necessary operations.

As the medical profession began to acquire more actual knowledge, to obtain more real dignity with less of the hocus-pocus of the Indian medicine man, the few surgical procedures were carried out by the same individual who prescribed the other remedies. This is the natural evolution—the needed and at that time relatively simple surgery was part of the care of the patient and as such was han-

dled by the doctor in charge. In fact, it is within the memory of a few men now practicing when the essentials of all medicine could be comprehended by one industrious individual, and when the limited surgery of the day might be included in his practice and at that, not unfairly to the patient. For a long time indeed the doctor who carried out the surgical procedures was a general practitioner who had special deftness with his fingers, who was a better mechanic than his fellows, and who in addition, had a particular liking for such treatment. He was still, however, a general practitioner.

With the advent of anesthesia, antiseptics, and asepsis the strides made by the surgeon became so great, the number of surgical procedures multiplied to such an extent and the variety of technical manoeuvres became so bewildering, that surgery became a specialty. Today surgery itself is even divided into various branches and so great is the variety that no one surgeon can be proficient in all of them. This has resulted in a condition which is a weakness of surgery as well as of all the so called specialties, namely—that they require so much study in their own peculiar details, so much concentration on technic, such a close view of a localized lesion, that there may be too little attention paid to the patient as a whole. The phrase "The operation was a success but the patient died" would not have been coined or if once spoken in jest, would not have persisted as it has, had there not been some basis for it.

Other than the cause just mentioned—lack of true medical perspective—is there any other cause on which we can lay the blame for this seeming though slight failure of surgery? I believe there is—the practice of surgery by too many physicians poorly trained or even untrained in the special technic required. Unfortunately the fees charged by many surgeons often justified by the skill used and the results obtained, though equally often we are sorry to say out of proportion to either, have resulted in the attempt of too

many poorly trained individuals to reap some of what they thought was an easy harvest. The remedy would seem to be obvious though difficult of attainment. The result of all this has been to cause some confusion in both lay and professional minds as to the exact relationship between the general practitioner and the surgeon. Too many people for instance, thinking they can take a short cut, go directly to a physician who has recently taken out a friend's appendix, report a pain in the right lower quadrant, and later with the memory of a painful hospital experience and a depleted pocketbook, recognize the same pain and finally are forced to go through the diagnostic procedures which they had tried to avoid.

In attempting to clear up this situation a little in our own minds, let us go back for a moment to first principles. A physician has as his first aim the alleviation of human suffering, whether this be the correction of a disease in an individual or the correction of an epidemic in a community, or any one of the other various forms in which his activities may be needed today. Here we are dealing with the relation of the physician, the surgeon, and the individual, and the subject with which this treatise deals, in one sense should have no existence because an accurate diagnosis is the one essential thing in order to cope successfully with the diseased individual. This, of course, is a problem in which either or both the physician and the surgeon are interested, for when an accurate diagnosis is made, the problem is then generally settled as there is a standard form of treatment for the larger number of diseases. It is only when this accurate diagnosis can be made that there is any reasonable expectation of success.

Surgery is only one method of treatment and we must do away with the type of specialist, surgeon or any other, where he as the old joke says "knows more and more about less and less," until he actually knows so much about so little that he has completely lost his balance, and is of absolutely no use in the treatment of a patient however good he may be in the treatment of a limited type of lesion. That type of person may occasionally be of value as a pure technician under the guidance of a competent medical man, but he has no

right to be treating the patient. A surgeon as well as a medical man, must have a sufficient knowledge of fundamental medicine and of the general principles of diagnosis so that he is able to evaluate the patient as a whole, as well as to give him the special treatment for which his training may fit him. Consequently, the subject of the borderline conditions between medicine and surgery, comes down to this—that both the medical man and the surgeon shall stand on the common foundation of a knowledge of the whole patient, that they shall both be able to diagnose intelligently, and cooperate so that the medical man on the one hand shall not lose the opportunity by procrastination or by lack of knowledge of what can be accomplished by surgery to give the patient the full benefit of any operative procedure. Nor should the surgeon because of lack of special training or inability to size up the whole picture, undertake something which is either more than the particular individual can stand, or likely to do damage greater than the benefit he is trying to bring about.

What are some of the things in which teamwork is necessary? As a matter of fact they are legion and only a few of them can be discussed here. There are two ways in which this subject might be deliberated at this particular point. We might outline some of the newer conditions in which with competent teamwork due to more accurate diagnosis, it is possible to recognize some rare condition such as adenoma of the parathyroids, and with skillful surgery work a miraculous cure, or we might try and evaluate for you the attempts to treat essential hypertension by partial adrenalectomy. It seems to me that in this group we can occupy ourselves more profitably with a discussion of some of the conditions where accurate teamwork should be more frequently called into play in general practice, and here I want to emphasize what I believe to be the essential part of this cooperation—that the condition under discussion shall not be *between* medicine and surgery, but shall be included within both, and that in such close cooperation better results for the patient may be achieved.

The first thing in which teamwork is necessary includes that very broad sub-

ject of chronic indigestion. This is probably one of the most important problems that come into the hands of the medical profession. The very large role which indigestion plays in the life of the nation has never been properly evaluated but when we realize that we are considering conditions from peptic ulcer to carcinoma of the stomach and large bowel, and all of the various phases of biliary tract disease, we realize it is a large field and I think the whole subject is one in which a very close cooperation between the internist and surgeon is necessary.

Peptic ulcer alone, whether in the stomach or duodenum, is probably the cause of more human misery than has ever been credited to it. It is the cause of many deaths not only due directly to the various complications but also to some condition which would never have originated, or at least not have been fatal had it not been for the ill health and lowered general condition due to the ulcer. If we add to this actual physical misery, the number of households depressed and the divorces from the bad temper arising out of it, it would take first place in the list of important diseases.

The etiology of this condition is not well understood. In fact, it is probably multiple but not *per se* a surgical disease though its complications are, and a recognition of these two facts by both parts of the team will result in a cooperation which will work for the good of the patient. I believe it is altogether too common to have a posterior gastroenterostomy done without adequate medical treatment in the first place, and if there is any patient that is difficult to handle surgically, it is the patient on whom a PGE has been done without relief. It is of the highest importance that all of the known factors coming into play should be considered and in so far as possible, remedied as an absolute necessity before surgery is in any way considered. This means a number of things: (1) the patient's general physical condition, particularly possible foci of infection, must be studied, (2) the patient's temperament, nervous tension, and fatigue must be considered, and (3) he or she must be educated to recognize the role which they play in this disease.

It is true that most people living under

the high tension of modern conditions are unable to change what may be their basic tendency toward the high tension existence. On the other hand, many people when they do understand the role played by this factor, can lift themselves up almost as if they were 'by their bootstraps,' and either by a change of business or by actual will power can lessen the tendency toward damage. The ability to regulate their lives so that frequent feedings and sufficient rest can be obtained, must be consummated, but when all has been done there will still be certain cases where there is no relief, and there is where the teamwork comes in.

It is just as essential for the surgeon, as for the internist, to know the whole background of a disease because I believe there will be a certain type of patient where symptoms will not be helped by either surgery or medicine, and I am not sure that there are not certain extremes in this class when it is wise to either avoid surgery completely or decide to do the radical operation the first time with the feeling that it will be the last regardless of results. Following operation, the surgeon and the internist both must follow these cases as they will continue to need supervision, and in a certain percentage of cases there will be some sequelae such as gastroduodenal ulcer, or continued bleeding which may require further surgery as the only method of treatment. It is essential also that the surgeon be particularly trained in this very complicated type of surgery because it some times happens that what is planned before the incision is made, cannot be carried out when the abdomen is opened. I believe the proper teamwork in these cases, perhaps will result in not less surgery, but less *unsuccessful* surgery. There may be fewer gastric ulcers which are allowed to go to the point where they are malignant when operation is finally undertaken, also fewer cases that have first one and then another, and then still another operation for relief of ulcer symptoms, until finally an autopsy shows what a grand mess was present at the finish.

We are given a very gloomy picture generally about gastric carcinoma, but I think that we are coming to recognize one bright spot in it, and that is, that

given a successful recovery from a gastric resection, both the prolongation of life and also the actual number of cures is very gratifying. This, of course, means just one thing to the medical profession; namely, an increased keenness to make an early diagnosis on the part of the internist and an increased skill and willingness to undertake radical surgery on the part of the operator.

If we now go from the upper to the lower end of the intestinal tract, we are confronted with various conditions where the successful outcome for the patient depends on both early diagnosis and properly applied treatment. One of the commonest conditions which we meet is intestinal obstruction, the most insidious form of which is the slow encroachment on the lumen of the bowel by a carcinoma. It is not uncommon to see a patient who calls the doctor in, only after several days without a bowel movement and with increasing distention and vomiting, and I am sorry to say, it is not uncommon to see the general practitioner spend still one, two, three or even four days trying to get something through the intestinal tract. I have two such patients in the hospital at the present time, one of whom went ten days without calling a physician while the other was treated for three days by the physician before reaching the hospital. It is true that the symptoms are apparently not too serious in many of these cases, but here safety for the patient lies in early diagnosis and in adequate surgery. In all of these cases it is entirely safe to use a barium enema, and in the vast majority of instances the diagnosis is at once evident. The mortality then, with early adequate treatment, drops from a pathetically high figure to one that is very satisfactory.

Another condition of the large bowel; namely, chronic ulcerative colitis, is also in the realm between medicine and surgery. During its early stages and entirely throughout in the milder cases, the disease is non-surgical, but in the more severe types there comes a time when surgery must be invoked, and in many cases it must be seized at once or it is too late. After the ileostomy has been done and the patient improves, there again comes the point where in certain cases the further need of operation has to be con-

sidered because of hemorrhage or persistent toxemia, where a colectomy is in order.

Megacolon is still another disease that must be handled by the team. Fortunately it is not common, and perhaps not of the greatest importance, but because not well understood it is very much in the borderline between medicine and surgery and deeply in need of the cooperation of both. A recognition of the fact that in certain cases it can be started by poor bowel habits, or that a severe chronic spasm of the anal sphincter may actually be the background, may in a few cases lead to a cure with very little surgical and properly planned medical treatment. In cases of a more severe degree, it may not yield to anything short of sympathectomy or a partial colectomy. However, the surgeon is not justified in trying these first any more than the medical man is justified in eliminating them entirely from the scheme of treatment, but I believe that in all cases, adequate medical attempt at cure should be undertaken. The judicious and continued use of enemata, cathartics, physostigmin, and proper diet may result in a cure or at least prove that surgery is necessary.

The last of the subjects which I consider under the broad picture of chronic indigestion, is damage in the biliary tract. Where a definite diagnosis of cholecystitis or cholelithiasis can be made, the prescribed treatment naturally follows. This is of course, surgery, but there are many cases which are borderline either in their diagnosis or in their treatment, and under these conditions again teamwork is essential.

I shall never forget the following case when I was a house officer at the Massachusetts General Hospital under Dr. Maurice Richardson, of beloved fame.

We were consulting with the medical service on which Dr. Frederick Shattuck was chief. There was a case of painless jaundice which had been admitted to the surgical side and no accurate diagnosis could be made, but with the age, the progressive nature of the disease, and the loss of weight and strength, there seemed to be little question but that there was a cancer of the head of the pancreas. Dr. Richardson and Dr. Shattuck always delighted in trying to get the better of each other, and Dr. Richardson in this instance put in a con-

sultation worded somewhat as follows "Do you doubt our diagnosis of cancer of the head of the pancreas? Do you advise operation? If so, why?" The answer came back "To the first question No To the second question, Yes, on the chance of human fallibility."

In this particular instance, the removal of a silent common duct stone and the cure of the patient made a tremendous impression on the minds of all of the young house staff.

Jaundice may point also to the possibility of some condition where surgery other than that of gall bladder or common duct may be indicated, and in obscure cases it is only after the utmost has been used in the line of medical skill that it is safe to say surgery is or is not indicated.

One of the conditions which bothers a good deal in every thyroid clinic, is the toxic patient who has been treated with iodine by his or her family physician without the full knowledge of what this is meant to do and without any cooperation with a competent thyroid surgeon. The effect of the iodine, very gratifying at first, wears off although giving the patient and the physician a false sense of security. The disease progresses with less and less alleviation from iodine, until reaching the surgeon's hands for final treatment, the patient may be badly toxic with a damaged myocardium and with surgery made more dangerous because of the inability to get the needed temporary response from preoperative medication. Here is one more instance where diagnosis must not only be accurate but the limitations of medical treatment and the success of adequate surgical treatment must be recognized early and appropriate treatment instituted. Of course, cases in which the patient does not report to any physician until the damage is extensive, need the most careful cooperation between the medical man and surgeon in order to insure success.

In the urinary tract as well, there are many conditions which are puzzling, and until "all of the packing is out of the case," it is impossible to say whether their ultimate disposal lies in the hands of the medical man or the surgeon. It often is true that the greatest possible degree of cooperation may be necessary

before the diagnosis can be accurately settled. Hematuria, for instance, should of course, respond to the dictum that blood coming from any orifice of the human body when not due to a known cause must be investigated, but can we say that because the surgeon sees a papillary tumor of the bladder on first cystoscopy that he must operate for a carcinoma? If there is not the recognition in a certain number of these cases that the patient is suffering from hypertension with chronic arteriosclerotic nephritis the surgeon may operate and find that the papilloma was actually the bleached out surface of a partially organized blood clot and that there is no surgical disease present at all.

One of the most bothersome situations which we have to face, is the elderly gentleman who comes with the complaint of frequency of urination, some slowness in voiding, and lack of sleep because of frequent nocturia. It has not been unknown to have such a patient operated on for the removal of the prostate when actually all his symptoms were due to hypertension and arteriosclerotic nephritis. It is equally embarrassing, I am told, to operate for prostatic obstruction because of some retention of urine with difficulty in voiding, and a slightly enlarged prostate to feel by rectum, and then have the bladder refuse to heal because of the failure of recognition of central nervous system disease.

At the Faulkner Hospital in Boston, we are trying what we consider a very interesting experiment of running a community hospital where we can give the patient the best possible service in accordance with the ideas which I have outlined in the first part of this treatise. We have all house cases admitted to the diagnostic service regardless of what their local physician may give as admission diagnosis. This is in charge of the medical department but includes all other specialties and certain things taken for granted. If the admission diagnosis is that of an acute abdominal emergency or some other condition automatically considered surgical, the surgeon as well as the medical man is notified at once on the patient's admission. If the acute abdominal emergency turns out to be an obscure pulmonary condition, as it has on one

occasion recently, we feel that the patient's best chance is in having both points of view. In this case, the roentgenologist had to be brought into play before the diagnosis could be made. If the condition is one which involves the possibility of less immediate surgical cooperation, the consultation is put in at once and the surgeon is supposed to check over the patient at his earliest visit. After the diagnosis has been settled, the vast majority of these cases are then naturally routine in their treatment, either a cholecystectomy on the surgical side, treatment for so-called catharrhal jaundice on the medical side, or either removal of a papilloma of the bladder or treatment of hypertension and chronic nephritis.

Even with the diagnosis in mind, the picture often is of sufficient complexity so that as in the case recently seen, the presence of a rather serious diabetes, a certain amount of myocarditis, and a gall bladder full of stones with a possible common duct stone has necessitated the continued cooperation of several individuals and as many points of view before the final agreement of all the physicians and the patient was reached. In other words, we do not consider any case in the realm between medicine and surgery, but all coming within the field where both surgeon and internist are interested in the patient and working toward the same end, each to use his own distinctive training toward that end. We feel that this arrangement is better for the patients than to have them admitted "medical" or "surgical" depending on the

admission diagnosis. It has been very interesting to note that at the Massachusetts General Hospital if a chronic appendix is admitted on the surgical side, he is seven times as likely to be operated on as though he were admitted to the medical side. This, of course, should not be. He should have the same study and the same conclusion reached on a diagnostic service, and as a result, the incidence of operation should be somewhere between the two extremes.

Summary

In closing then, let me repeat what I believe to be the fundamental principle. A physician has the alleviation of human suffering as his first and sole aim. The field of medicine is so broad that no one individual can comprehend it all. This necessitates the formation of specialties, but no specialty can justify its existence if it allows the physician to become so narrow that he is unable to treat the condition in which he is interested without benefit to the individual as a whole. No condition is ever a borderline condition *between* medicine and surgery, but a great many should be embraced by both medicine and surgery in order to give the patient the best possible treatment. No surgeon or any other specialist has any right to practice medicine unless he is able to accomplish two things—to treat the patient as a whole with a reasonable degree of skill and to handle his particular specialty with the highest possible degree of skill.

279 CLARENDON ST.

ELECTIONS AT ROCHESTER AND MONROE COUNTY

DR. WILLIAM A. SAWYER has been re-elected president of the Tuberculosis and Health Association of Rochester and Monroe County.

The action was taken on Oct. 30 at a meeting of the board of directors who also re-elected Joseph P. MacSweeney and Dr. Edward G. Whipple, vice-presidents; Frederick L. Higgins, treasurer, and Allan C. Ross, assistant treasurer.

Mark B. Furman, district superintendent of schools, of East Rochester, recently elected chairman of the County Health Committee of the association, was elected vice-president and Dr. George E. Sanders of

Greece was elected assistant treasurer. Health examination of all students was urged.

An adequate public health nursing service was cited as the outstanding need in Monroe County outside of Rochester. The urgency of securing more public health nurses was stressed in reports presented by Dr. E. G. Whipple, chairman of the Public Health Committee of the Medical Society of Monroe County; Dr. Charles G. Lenhart, president of the Monroe County Health Officers' Association; Dr. B. R. Wakeman, district state health officer, and Dr. B. J. Slater, representing the Tuberculosis and Health Association.

THE NOVOCAIN PACK

A Contribution to the Therapy of Fresh Accidental Wounds

MILIO FRITZ, M D, *Brooklyn*
Junior House Surgeon Brooklyn Hospital
and

E K TANNER, M D, *Brooklyn*
Attending Surgeon, Brooklyn Hospital

In emergency ward work, no small percentage of cases is concerned with comparatively fresh gashes involving superficial tissues, necessitating a varying number of sutures after hemostasis and cleansing have been accomplished. This article does not include wounds so extensive that shock is a dominant part of the picture, or wounds which demand hospitalization for treatment.

Cleansing such small wounds and suturing them is usually undertaken without anesthesia since the pain, although severe, is of such short duration that it can be borne. Yet with children and in the very sensitive, such treatment has seemed unnecessarily brutal.

Bernard Fantus¹ in his article on the treatment of Fresh Accidental Wounds says, "If anesthesia is required for the treatment of the wound, nitrous oxide inhalation is the agent of choice."

In a criticism of this, one who signs himself "M D" says

For many years I have been infiltrating the edges of such accidental wounds after a preliminary cleansing to facilitate a proper painless cleansing, and placing of the necessary stitches. When the needle for infiltration is started through the fresh wound, it is painless. I have never seen any other physician use local anesthesia in such a case and after many trials, I can see no unanswerable objections to the method.

The above statement was of interest to us in the Brooklyn Hospital and, whereas, it was not possible on the emergency ward to use nitrous oxide for small wounds, a trial was given to the method of infiltration. Three disadvantages were found in this method: (1) The "preliminary cleansing" was often painful. (2) The insertion of a needle into the wound edges, in addition to the possibility of introducing infection, was painful. (3) Infiltration often distorted tissues in such

a manner as to interfere with a good cosmetic effect.

On one occasion a young man came into the emergency ward with a deep laceration on the hypothenar eminence of his left hand, which was very dirty. In view of the contamination of the wound, infiltration was clearly contraindicated, but since the nurse had already opened two vials of one per cent novocain and since it seemed a shame to waste it, a strip of gauze was laid in the wound and the novocain poured on it with the hope that anesthesia might be obtained. The novocain pack was allowed to stay in place for about eight minutes while the nurse and doctor scrubbed and got ready the tray preparatory to suturing the wound. The wound was then thoroughly cleansed and five sutures taken without the patient experiencing any pain at all.

Since then, in all such cases, the novocain pack has been used successfully. Lacerations of the fingers, eyelids, face, cheek, chin have all been treated without pain—the area of effective anesthesia extending about 1 cm. beyond the wound edges.

The following three cases are of particular interest.

Case I A little girl, 17 months old, was knocked against the door handle of a car when it was struck from behind by another car. She received a laceration about four inches in length on her left zygoma extending from the external canthus onto the cheek. A novocain pack was used and the suturing was absolutely painless; the child crying only when sterile gauze was placed over the wound and the eye. The child did not move so a fine cosmetic result was made possible.

Case II A negro received a razor gash which involved his right upper eyelid cutting down to the conjunctiva but not involving it. Seven sutures were painlessly

inserted after the novocain pack had stayed in place six minutes.

Case III. A boy had grasped an open knife in his left hand receiving lacerations of the flexor surfaces of the distal phalanges of his third and fourth fingers. A novocain pack was applied to the third finger, but not to the fourth. Suturing of the third finger was painless, but this was not the case where the fourth finger was sutured up.

The only possible contraindication has been the freely bleeding wound which washes out the novocain so that it cannot be effective, and often this can be controlled by topical application of 1:1000 adrenalin.

It was believed that a five per cent solution of novocain in normal saline would act more quickly and extend the area of effective anesthesia. Such a solution was made available, and whereas the area of effective anesthesia has not penetrated further than 1 cm. from the wound edges, the time for such effect has been cut from eight to about five minutes.

Since this method of local anesthesia, others in the hospital have applied it successfully, and in the few cases where complete anesthesia was not obtained owing to hemorrhage or other reasons, they feel that the pain was much reduced.

Summary

1. Small fresh accidental wounds have been rendered anesthetic by the application of a novocain pack (1%) for 5-8 minutes, and five per cent in 5 minutes.

2. Cleansing and suturing of such wounds was done without pain, thus ensuring better working conditions for the surgeon, better cosmetic results for the patient, and no pain for the latter.

3. The only contraindication is the freshly bleeding wound in which it can be used after hemorrhage has ceased, or has been controlled by topical application of 1:1000 adrenalin.

4. This method has the advantage of simplicity over the nitrous oxide method, and it obviates the danger of infection, the pain of preliminary cleansing, of the first needle prick, and the tissue distortion of the infiltration method.

5. Area of effective anesthesia extends about 1 cm. beyond wound edges.

BOOK REVIEW

(For other reviews see pages 1189 and 1238)

The Patient and the Weather. By William F. Petersen, M.D., with the assistance of Margaret E. Milliken, S.M. v. 2. *Autonomic Dysintegration*. Quarto of 530 pages, illustrated. Ann Arbor, Mich., Edwards Brothers, Inc., 1934. Cloth, \$6.50.

Volume II of the triad, "The Patient and the Weather," deals with what the author calls "autonomic dysintegration" in which he presents observations made on individuals who are unusually responsive to the environment. He has had the cooperation of several colleagues. Especial attention is paid to a possible explanation of headache in general, migraine, epilepsy, asthma, gastric ulcer, arthritis and urticaria.

Petersen made a detailed chemical and clinical analysis of patients suffering from these diseases. According to him they occur in unstable individuals, particularly affected by meteorological conditions which are

capable of inducing vasomotor spasm with consequent injury to the organs of the body. The author feels that there is a definite relationship between the person, the chemical state of the blood, and meteorological changes to account for the attacks of migraine, epilepsy, asthma, etc. During the period of change from one type of air to another, when it is necessary to make a speedy physiological adjustment in the body, there is apt to occur an alkalosis with resulting spasm of the blood vessels.

There is a great deal of evidence to substantiate Peteren's observations in the above diseases, but when the author considers the neuroses in the same category he undoubtedly will find few psychiatrists or psychoanalysts to be in accord with him. His discussion of the neuroses leaves a great deal to be desired.

EDITORIALS

While the Patriot Sleeps¹

The restless modern spirit has not the patience of the ancient. We hurry along roads toward goals of whose form and character we are seemingly unaware. As we watch the current scene, we note new evidence in many social welfare programs to create a fixed proletarian class and establish a state of perpetual dependence among groups in our population.

Recently orders to PWA limited jobs to those who were on relief.¹ They who had been strong enough to carry on with only the barest sort of subsistence, preferring this to public aid, found themselves penalized for their self sufficiency. We note social workers endorsing a low dietary regime based on minimum quantities of poorest quality of foods, on the one hand, and on the other asking for a costly, inferior system of medical care to combat the resultant ill health. Millions are spent on governmental health surveys which eventually will reveal nothing that is not generally known, but moneys to remove and replace breeding spots of disease and corruption are not given, or spent. In Westchester County it is proposed to spend almost half a million dollars in stamping out malaria, to the consternation of the local health officials

who are apparently unaware that they are faced with a malaria problem!

The living standards of American labor have sunk appallingly in the past six years, but the proposals are nevertheless made, that the slim pay envelopes of labor shall be depleted further to provide medical care for a small percentage who undoubtedly could more properly and at less expense be aided out of general tax funds.

Contemplating these trends we fear the loss of one of our proudest rights which the American political set-up heretofore has proffered to every one,—the right of self improvement without obstacle or hindrance by government. The establishment of a dominant social bureaucracy,—which must come if sickness insurance comes,—under which the status of labor and of medicine would be fixed, will lose to both the inherent right to advance and to improve their level of existence and their degree of comfort and security in the community.

Any measure designed primarily to mitigate a situation does not permanently improve it. As physicians we know that a palliative is seldom curative.

Consider the bureaucracy itself and what it will encompass. President Butler of Columbia University recently told us how taxation brings in its train fundamental changes in governmental struc-

¹ Editorial, *New York Medical Week*, November 16, 1935

tures. The reality in which human lives and the human mind move and live is the reality of long, unchanging tradition. American political ideology being the reality which it is, and we Americans being what we are, we must comprehend what a bureaucracy, such as would result from health insurance, would mean politically in our country. The resulting political machine which would enroll professional men, labor, industrial and social workers in a self interested group, would make the old time labor or veterans' organizations and other political blocks seem Lilliputian in comparison.

While Liberalism generally is under attack, when our democracy is being insidiously undermined, as Mark Sullivan² points out in his comparison of the present state of our electorate with that of the Russian Kulak farmers of 1916,—as “not knowing that all around them were forces, and men who, within a year, would destroy the order of society * * *,”—then let us beware lest in our striving for a theoretical result we are not forced to swallow a bitter pill,—entailing among other things the loss of our liberties,—because it is temptingly coated by false arguments and fallacious reasoning.

High Time For A Halt

Recent developments in the milk campaign indicate that commercial advertising methods and health education do not mix any better than oil and water even when their union is authorized by the government. Beginning with sound and reasonable claims, the state's copy-writers fell into the usual pitfalls of exaggeration and distortion. From an excellent food, milk became first a reducer and then an alkalinizer. The next stage in the process of apotheosis by advertising is usually acclaim as a cure for cancer, tuberculosis or hypertension.

Probably such gross fraud would never have been essayed in this particular instance. In any event, this JOURNAL and

subsequently the J.A.M.A. pointed out the folly of trying to sell milk as a “patent medicine” or “cure for several complaints.”

Following these statements, the New York State Commissioner of Health agreed that “any effort to sell milk as a medicine is not a sound appeal.”

When the drink-more-milk campaign was inaugurated, many physicians felt that it was more apt to increase profits for the milk industry than to better public health. The main reason why many families do not use milk is that they cannot afford it; and the state drive has done nothing to bring it within their means. Even from the purely educational viewpoint, the methods employed suggest far more devotion to the principles of high pressure salesmanship than to reasoned, accurate instruction. Is it any wonder that the profession distrusts state control!

The Panel System Evolves

Profound changes in medical practice are taking place and are hardly noticed. These changes are bringing problems which we shall soon be obliged to answer. For example, since the enactment of the new Workmen's Compensation Law, a panel system is coming into being (created under the law), by the County Medical Societies. There are well founded rumors that the TERA work will be done by physicians on these same panels. This will necessitate that men who did not enroll for compensation work will have to do so, if they want to work for the TERA. There are panels of approved groups in the Health Department of New York City.

Who pays the expense of creating and administering these panels? If the County Societies do so, they maintain their autonomy; but if they pass this power over to the State, then and there they increase the scope and horizon of State Medicine. Who pays the piper calls the tune!

There is no question more pressing for solution. The answer largely will determine how much further into the territory

² Mark Sullivan, New Deal to New Order.—*New York Herald Tribune*. November 17, 1935.

of the independent medical field State medicine shall go

Progress at Three Cents a Day

A number of practitioners who have had experience with the group hospitalization insurance offered by the Associated Hospital Service have expressed their satisfaction with the workings of this plan. Patients who might otherwise be compelled to defer treatment are able to enter a hospital when necessary without applying for charity or contracting debts. The physician is more often and more promptly paid because available funds are not eaten up by institutional charges.

Naturally there can be no claims of perfection for so new a system. Some Roentgenologists, for example, fear that the inclusion of "ordinary Roentgenograms" in the insurance agreement may result in exploitation of their services. Offsetting this possibility is the fact that organized medicine is represented on the voting board of the Associated Hospital Service and the latter may terminate its contract, after thirty days' notice, with any hospital guilty of a breach of good faith. No institution with any foresight will sacrifice a source of regular income for an occasional illicit profit at the expense of its medical staff.

Cities which have not yet inaugurated group hospitalization services are in a position to benefit by the experience of Greater New York and other communities in which such plans have been in operation for various periods of time. Provision for hospitalization nullifies one of the principal arguments for obligatory pre-payment for sickness by writing off the item which is most likely to overwhelm middle and working class patients. Unlike compulsory health insurance, group hospitalization does not interpose a lay bureaucracy between doctor and patient nor disturb the relationship of the profession to the public in any way. It neither raises taxes nor lowers income to any material extent. This is constructive reform, designed to encourage indi-

vidual independence rather than create a class of perpetual dependents on the state.

The Red Cross Roll Call

The work of the Red Cross in peace time, though less dramatic than during a war, is nevertheless of great benefit. The Red Cross nurse is a familiar figure in hundreds of our communities. Public health nursing, safe-guarding communities against epidemics, and other beneficent health activities commend this organization to us. This year saw their nurses on duty in the dust storms of Kansas, Texas, Colorado, New Mexico, and Oklahoma, as well as during the floods in our own state.

We commend the faithfully performed duties, and ask support for the replenishment of the funds of this organization.

Cholecystitis and Hepatitis

What relationship, if any, exists between cholecystitis and hepatitis has been the subject of much speculation since the publication of Graham's histological studies in 1918.¹ Graham concluded from his investigations that infections of the gall bladder resulted from a primary hepatitis. Subsequent reports by other observers substantiated the presence of changes in the liver where cholecystitis was present but questioned the causal relationship of the former to the latter. Some considered the hepatic pathology as secondary to the lesion in the gall bladder² while others felt that it was not possible to determine which was cause and which was effect.³

With the development of the finer methods of histological technic came the impetus to reinvestigate the basic question of the presence of hepatitis as an associated finding in acute and chronic chole-

¹ Graham, E. A. Hepatitis. A Constant Accompaniment of Cholecystitis, *S G and O*, 26, 521, 1918.

³ Heyd, C. G., MacNeal, W. I., and Killian, J. A. Hepatitis in Its Relation to Inflammatory Disease of the Abdomen, *Am J. Obs and Gyn*, 7, 413, 1924.

cystitis. Colp, Doubilet and Gerber⁴ state that a true estimation of cellular degeneration cannot be determined by ordinary routine histological measures. A granular appearance of the cytoplasm in itself is not evidence of a true degenerative condition, and the presence of fat in the liver cells might be a normal physiological condition. The finding of periportal cellular infiltrations in the presence of cholecystitis cannot be used as a basis for stating that gall bladder infections are accompanied by hepatitis since this pathological phenomenon has been observed too frequently in connection with extrahepatic lesions wherein the biliary tract is uninvolvement.^{5,6}

Since the earliest evidence of cellular degeneration is shown by changes in the mitochondria, Colp conducted his studies of the liver parenchyma, placing special emphasis on the finer cytology. A detailed investigation of forty cases of cholecystitis without jaundice failed to reveal any changes in the liver cells which could possibly coincide with those found in hepatitis wherein the inflammatory process in the framework is associated with diffuse parenchymal changes. On the other hand, where icterus was present prior to operation, focal degeneration of the hepatic cells was sometimes noted, but the presence and extent of such changes were dependent upon the duration of the biliary stasis and were not related to the lesion in the gall bladder.

It may be assumed, from the observations of Colp and his associates, that destruction of liver substance is to be looked for as a sequela of protracted biliary obstruction, and is not to be accepted as a concomitant of cholecystitis. The avoidance of hepatitis therefor would seem to depend upon the earliest relief of the biliary stasis and not upon the

removal of an offending gall bladder *per se*. Finally, the continuance of the academic discussion concerning the relationship of hepatitis and cholecystitis must rest, for the time being, pending possible future determining analyses based upon histological data.

Uric Acid and Marrow Activity

That gout is the result of a disturbance in the uric acid metabolism is an established fact but the predisposing cause of the disease has remained obscure. Always considered a "rich man's disease," it was associated naturally with the imbibing of excessive amounts of alcohol and the ingestion of foods rich in purines. Williamson,¹ however, found that only fifty per cent of his patients were heavy drinkers and he noted that of the remainder four per cent were total abstainers. The continued high output of uric acid in gouty sufferers placed on purine-free diets would tend to indicate that exogenous sources could not wholly account for the increased production of uric acid in these patients.

Krafka² in an experimental study, showed that beside the formerly described sources of endogenous uric acid, another one existed in the extruded nuclei of the normoblasts which are destroyed during the maturation of the erythrocytes. The results of his work would speak for a complete correlation between marrow activity and uric acid production. Riddle³ corroborated this viewpoint by demonstrating that potent liver extracts which enhanced the production of red cells also increased the output of uric acid. Sears⁴ and Fitz⁵ report clinical cases of gout

appearing after liver therapy for anaemia. The "gouty diatheses" observed in cases of polycythemia would further tend to substantiate the close association of the marrow system and uric acid metabolism.

Krafka⁶ states that anything which stimulates the erythropoietic system must be considered as an etiological factor in the production of gout since it increases the uric acid content in the body and that, in the treatment of this disease, hemolytic and hematopoietic agents must be used with discretion. He also feels that gout as such has not become extinct but "now goes about disguised under other names."

CURRENT COMMENT

"THE MUCH DISCUSSED Social Security Act was finally approved by Congress on August 14, 1935. * * * This act is to provide for the general welfare of the people by the establishment of a system of Federal Old Age benefits, and to aid the several states in making more adequate provisions for aged persons, blind persons, dependent and crippled children, maternal and child welfare, public health and the administration of their unemployment compensation laws. * * * The new law is a laugh on Scientific Medicine * * * even now many men in the medical profession may be dazzled to blindness by the announcement that under the S.S.A. comes an authorization for an annual appropriation of eight million dollars to be allotted by the Surgeon-General of the Public Health Service with the approval of the Secretary of the Treasury, the States, Counties Health Districts and other political subdivisions, to aid them in establishing and maintaining adequate public health services. * * * To this appropriation comes another two million dollars, annually to cover the pay and prerequisites of Personnel of the Public Health Service detailed to cooperate with Health Authorities of any state, and for investigation of disease and problems of sanitation. To fulfill the requirements of the act, the services of the Medical Profession will be absolutely necessary; therefore, it is vitally important that every physician be familiar with those provisions that concern the practice of medicine."

⁶ Krafka, J.: A Neglected Factor in the Etiology of Gout, *J. of Bone and Joint Surg.*, 17, 1049, Oct. 1935.

"Even the dullest economist discerns readily the fist of politics clutched in the cash box in the appropriations of this provision. * * * It is easy to prophesy that when it comes to the working out of the provisions of the plan, the 'stricken' who get most aid will be those who profited the greatest through the Maternity Act appropriation, that is, the politically stricken henchmen of Big Politics who need jobs. The Shepherd Towner Act bought no diapers or swaddling clothes for infants, nor sheets, night gowns, fuel or shelter for mothers, but it did buy all these and more for the men and women, paid by heavy taxes out of the pockets of burdened taxpayers, who went along telling mothers how to feed children if they had food to give them. It is noteworthy that none of these tax-wrested millions were turned over to the Medical Profession to administer. We, therefore, feel that it is up to the A.M.A., State Medical Societies and local County Medical Societies,—all must be actively interested in the administration of the provisions of this Act; interested enough to insure that the high ideals of Economic Security for the individual provided by the Act is attained. It should not be just another Noble Experiment."—Editor, *Bulletin of the Central Medical Council of Brooklyn*, November, 1935.

"ORGANIZED MEDICINE was among the first of the educational organizations to utilize the radio in bringing information about public and personal health to the American people. Since 1923 the use of the radio for health education purposes has been a consistent policy of the medical profession."—W. W. Bauer, Director, Bureau of Health and Public Instruction, A.M.A.

SIR KINGSLEY WOOD, the minister of health (England) at a meeting recently of the London Insurance Committee, which is a committee of physicians which administers the panel system, said, among other things, "that the prescriptions which during the year of his chairmanship had been 4,377,000 had risen to 8,482,000. The English, he thought, were apparently becoming 'a nation of confirmed medicine drinkers.'" According to the London letter to the A.M.A., November 16, 1935, the writer states, "Under the panel system it (prescription) is to be had without payment, and physicians do not care to endanger their popularity by refusing to prescribe. Of course the placebo has always existed in medical practice and sometimes is unavoidable; but when it is to be had only for the trouble of visiting or sending to the panel physician, the result is obvious."

Society Activities

Executive Committee

The Executive Committee has directed the publication of the following:

REGULATIONS GOVERNING MALPRACTICE DEFENSE AND GROUP INSURANCE

Adopted by the House of Delegates of the Medical Society of the State of New York at the Annual Meeting, April 3, 1933

MEMBERS NOT INSURED UNDER THE GROUP PLAN

The Medical Society of the State of New York will furnish to its members the services of the Counsel of the Society in actions brought for alleged malpractice, error, or mistake done or claimed to have been done in the legitimate performance of the duties of their profession as physicians under the following regulations:

The Counsel of the Society will serve as attorney in all actions for alleged malpractice, brought against members in good standing, who must be so certified by its Secretary, excepting as follows:

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society.

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed during a period when they were not in good standing, according to Chapter XIV, Section 4, of the By-Laws.

Members shall not be entitled to malpractice defense while residing and/or practicing medicine or surgery outside of the territorial limits of the State of New York.

The Society will not undertake the defense of any member who, after consideration by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not complied with the recognized ethical laws in regard to these cases.

Members shall agree not to compromise any claim against them, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claims against him, he shall reimburse the Society

for the expense incurred in undertaking his defense, and in default thereof, he shall be deprived of further privilege of malpractice defense.

The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making payments for any purpose whatsoever.

Members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing. They shall also furnish the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the attorney of the State Society.

In the event of any difference of opinion between a member of the Society and the Counsel concerning the eligibility of a claim for defense, or any other matter having to do with malpractice defense or indemnity, all details shall be presented to the Insurance Committee to be referred with recommendations to the Executive Committee of the Council for its decision.

The foregoing regulations are subject to such change as may from time to time be authorized by the Executive Committee of the Council or the House of Delegates.

MEMBERS INSURED UNDER THE GROUP PLAN

All members in good standing shall be entitled to malpractice defense and indemnity in the Group Plan of Insurance on payment of the premium due on the policy selected, but the amount of insurance protection granted to any member may be limited at the discretion of the Executive Committee of the Council, subject to petition for reconsideration.

When upon the final completion of the defense of any suit or claim it shall appear to the satisfaction of the Executive Committee that the medical procedure, conduct or attitude of the member involved was such

that it could not have the approval of competent medical opinion generally and that the continuance of such medical procedure, conduct or attitude would constitute a burden to the Society's Group Insurance Plan more hazardous than that contemplated in what is generally accepted as the competent practice of medicine, the Society shall have the right to withdraw from such member the privilege of renewal of his indemnity insurance under that Plan. Nothing in this rule shall deny such member a rehearing by the Executive Committee. This rule shall also not abrogate such member's right to subsequent malpractice defense by the Society.

If an assured shall fail to maintain in good standing his membership in the State Society, according to Chapter XIV, Section 4, of the By-Laws, the policy, so far as it applies to such assured, shall be cancelled as of the date upon which he ceased to be a member in good standing. A notice to this effect shall be mailed to the member's last address, and the Company will return upon demand and surrender of his certificate, the unearned premium due him on account of such cancellation. If the member is reinstated by payment of dues, the former policy cannot again be put in force but the member can secure a new policy under the same conditions as if he were a new member of the Society. This rule shall become operative if and when it is written into the policy of the Group Plan.

The Group Plan of Insurance shall insure a member within the limits of his policy against loss growing out of suits or claims for malpractice, error or mistake, committed or alleged to have been committed by an insured member in the legal practice of his profession or by any assistant of such a member, whether in institutional or private practice, in the treatment or care of a patient previously seen and diagnosed by such a member and for whom the member has directed a course of treatment or care.

The Group Plan of Insurance shall not cover the liability of an insured member on account of the use of x-ray for therapeutic treatment, the employment of partners, associates, assistants, technicians or nurses to practice medicine in his name independently of his personal diagnosis and specific instructions as to the treatment or care to be given, nor shall it cover the liability which such a member may have by reason of his ownership in whole or in part of any association, partnership, clinic, hospital, sanitarium, dispensary or any enterprise other than his personal practice of medicine therein. The liability for such ownership constitutes additional hazards not con-

templated under the Group policy or rates, and losses on account thereof shall not be charged against the experiences of the Group Plan. Protection against these hazards shall, upon request and the payment of an additional premium, be furnished by the carrier by endorsement upon members' Group Plan Certificate or under an additional policy of insurance when necessary.

The Group Plan policy shall not cover the liability which an insured member may have on account of injury to patients from causes other than medical treatment, care or advice, nor for injury to persons other than patients from any cause whatsoever. Protection on account of such losses can only be had under general liability or workmen's compensation insurance.

When in the course of duties imposed upon him as a medical officer of the State, or any political sub-division thereof, an insured member shall be required to render medical opinion, he shall be fully protected under his Group Insurance against the consequences of such an opinion provided it shall have been given to competent authority and not made public by him.

All members of the Counties in Greater New York and Rockland, Westchester, Nassau and Suffolk, desiring insurance protection in the Group Plan of the State Society, shall secure that protection through the Authorized Indemnity Representative of the Society, Mr. Harry F. Wanvig.

MEMBERS INSURED BY COMPANIES OTHER THAN THE CARRIER OF THE GROUP PLAN

A member who elects to secure malpractice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York. If the member desires this service under the circumstances, all the regulations as detailed above applying to members not insured under the Group Plan must be observed. At the time the action is begun, and not later, the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, date of policy and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the Carrier of the Group Plan in like instance. Also that he shall not be required to consult with or receive instructions

from the Company as to the manner of defense, and that the Company will accept his opinion on the final disposition of the action.

As Companies other than the Carrier of the Group Plan usually compel the holders of their policies to accept defense by the Legal Counsel of the Company concerned, the above would not apply. It is essential, however, that members so insured shall also enjoy the benefits of the services of the Counsel of the Medical Society of the State of New York, if desired; but it is obvious that such service will be restricted by the rule of the Insurance Company cited above.

Malpractice Insurance Committee

The Executive Committee of the Medical Society of the State of New York have turned over to the Insurance Committee the following letter:

November 1, 1935

Daniel S. Dougherty, M.D.,
2 East 103rd Street,
New York City

Dear Doctor Dougherty:

A number of physicians who are members of the County Medical Association, and in turn of the State Association, are interested in renewing their Malpractice Insurance in the Aetna Insurance Company or in writing it on a plan that we have presented to various individual members, at a net cost of approximately \$22.40 for \$5,000/15,000 limits in this territory.

These doctors have asked us to write you and find out if they are within their just rights by so doing and if it will have any effect on their status as members of the New York State Association.

Will you kindly give us the details?

Very sincerely yours

The above letter brings to the attention of the Insurance Committee the significant fact that many of the members of the Medical Society of the State of New York are unfamiliar with the privileges and rights that they enjoy as members of the State Society.

1. A member in good standing who is not insured against malpractice is entitled to malpractice defense by the Counsel of the Medical Society of the State of New York.

2. A member in good standing who is insured against malpractice with the official carrier of the Group Plan is entitled to defense by the Counsel of the Medical Society of the State of New York.

3. A member who elects to secure mal-

Thus while the Legal Counsel of the Medical Society of the State of New York cannot be required under these circumstances to assume control of the defense or to appear as associate counsel, he shall be ready to render to the Counsel of the Insurance Company, if requested, a consultant's opinion and advice provided the Company concerned will compensate him for this service in the same manner as the Group Plan Carrier would do if the member was thus insured.

All previous resolutions heretofore adopted, pertinent to malpractice claims and defense, are hereby rescinded.

practice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York, but with the following provisions and limitations:

At the time the action is begun, and not later, the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, the date of policy, and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the carrier of the Group Plan in like instance. Also that he shall not be required to consult with or receive instructions from the Company as to the manner of defense, and that the Company will accept his opinion on final disposition of the action.

(Regulations Governing Malpractice Defense and Group Insurance: Adopted by the House of Delegates of the Medical Society of the State of New York at the Annual Meeting, April 3, 1933.)

The Insurance Committee are taking this opportunity of bringing once more to the attention of the members the basic fact that when a member insures in a company other than the official carrier, legal defense by the Counsel of the Medical Society of the State of New York is furnished with the above conditions, as adopted by the House of Delegates.

CHAS. GORDON HEYD, M.D., *Chairman*

Committee on Workmen's Compensation

A PUBLIC HEARING has been arranged by the Industrial Commissioner, Elmer F. Andrews, on the schedule of medical fees in

connection with Chapters 258 and 930 of the laws of 1935. This is the schedule recently submitted by the President of the

Medical Society of the State of New York as required by law. The hearing will give all parties interested, physicians, labor, insurance carriers and others an opportunity to discuss the schedule before the Commissioner takes formal action to adopt it as prepared or as it may be amended. The date set is Tuesday, December 3, 1935, at 10:30 A. M. in Hearing Room No. 1, 80 Center Street, New York City.

OCCASION for personal contact, direct or written, between physicians giving medical care to injured workmen and officials of insurance companies writing compensation insurance will frequently arise. For the convenience of the physicians, the State Committee has sought and secured an official list from the Compensation Insurance Rating Board of representatives of the insurance companies who are charged with the responsibility of authorizing special arrangements when needed.

It is recommended by the Committee that the following list be preserved carefully by all physicians for future reference.

**AETNA LIFE INSURANCE COMPANY
AETNA CASUALTY & SURETY COMPANY**

Medical News

Broome County

BINGHAMTON HOSPITALS and surgical methods were given a high rating by Dr Temple S Fay, professor of Neurological Surgery at Temple University's School of Medicine at the regular monthly meeting of the Broome County Medical Society in the Binghamton Club on Oct 1

Cattaraugus County

THE PAPERS by Dr Donald R McKay and Dr Raymond F Rosedale, on pneumoconiosis, at the October meeting of the Society Tuesday, the 8th, closed the series of lectures on silicosis and allied condition, given to the members of the Cattaraugus County Medical Society by members of the staff of the Buffalo City Hospital. The meeting was held in the Colonial Room of the Olean House, following dinner. Two new members were admitted.

Chautauqua County

THE REGULAR FALL meeting of the Chautauqua County Medical Society was held Sept 25 at Newton Memorial Hospital in Cassadaga. Forty were present for the dinner which preceded the technical discussion.

A paper on Surgery of the Gall Bladder was given by Dr Howard M Clute of Boston.

Dr T H Shinnahan of Jamestown presided.

Chemung County

THE FUNCTIONS of the county medical society were interestingly presented by Dr Joseph Lawrence, Executive Director of the State Society, at the October meeting of the Chemung County Medical Society at the Elmira City Club.

Cortland County

DR CHARLES D POST of Syracuse University was the guest speaker at the meeting of the Cortland County Medical Society on October 18.

Dutchess-Putnam Counties

DR ABRAHAM KAPLAN, neuro-surgeon of Mt Sinai Hospital, New York, addressed the Dutchess-Putnam Medical Society in Poughkeepsie on Nov 13 at the Amrita Club, on "The Diagnosis of Operable Intracranial Lesions."

Essex County

AT A RECENT MEETING of the Essex County Medical Society at Moses Ludington Hospital, Ticonderoga, Dr J A Gers of Lake Placid was elected president, Dr John Breen of Schroon Lake vice president, and Dr L H Grus of Ticonderoga, secretary treasurer.

A scientific program was presented with papers by Dr Waite and Dr H J Harris of Westport on 'Undulant Fever'. Following the meeting a luncheon was served.

Franklin County

THE ANNUAL MEETING of the Medical Society of the County of Franklin was held at the Alice Hyde Memorial Hospital, Malone, October 23. Luncheon was served in Hotel Flanagan. The following officers were elected for 1936: President Dr E N Packard, Vice Pres, Dr Daisy H Van Dyke, Sec-Treas, Dr G F Zimmerman, Censor for three years, Dr E M Austin, Delegate to N Y State Meeting, Dr C C Trembley, Alternate, Dr J E White.

It was voted that four meetings be held each year, in February, May, August and November. Committees were appointed to review qualifications for compensation work.

Fulton County

DR ELDRIDGE H CAMPBELL of Albany, formerly of the Johns Hopkins Hospital in Baltimore, was the principal speaker at the meeting of the Fulton County Medical Society on October 17 in Johnstown. His topic was "Early Diagnosis of Brain Tumors."

Genesee County

ELIMINATION OF THE SERVICES of the city physician and surgeon and division of the relief work among all the physicians of the city was proposed at a meeting of the Genesee County Medical Society on Oct 1 at the Hotel Richmond in Batavia. A committee was appointed to confer with the Common Council regarding the proposal which would enable those on relief to call their family physicians, the cost to be paid from city, state and Federal funds.

Kings County

INTERESTING PAPERS on pulmonary tuberculosis were presented before the Kings County Medical Society at its headquarters on Bedford Ave on Oct 15, by Dr E J

O'Brien of Detroit and Dr. Foster Murray of the Kingston Ave. Hospital.

Monroe County

MORE AGGRESSIVE health legislation, better enforcement and public education are necessary to curtail blindness, Dr. Harry S. Gradle of Chicago, chief of staff of the Illinois Eye and Ear Infirmary, told the Monroe County Medical Society on Oct. 15 at the Rochester Academy of Medicine.

Montgomery County

THE MEDICAL SOCIETY of the County of Montgomery and the staffs of St. Mary's Hospital and the Amsterdam City Hospital met on Oct. 30 in St. Mary's Hospital at Amsterdam. Dr. William R. Rathbun, Canajoharie, president of the society, presided and Dr. P. J. Fitzgibbons, president of St. Mary's Hospital staff and Dr. R. J. Knapp, president of the City Hospital staff, presided for their staffs.

Addresses were given by Dr. E. K. Cravener of Schenectady and Dr. H. Jackson Davis, director of medical care for the TERA.

Nassau County

THE NASSAU AND WESTCHESTER County Medical Societies held a joint dinner-meeting at the North Hempstead Country Club at Port Washington on Oct. 29.

New York County

AN ATTACK by Dr. Simon Flexner on the Kolmer and Brodie-Park vaccines for infantile paralysis appeared in the November issue of *Science*, and was played up prominently in the New York papers. The virus in the vaccines "is either inactivated (destroyed) or merely reduced in concentration," said Dr. Flexner. "When the virus is actually destroyed, it no longer possesses immunizing power; when it is reduced in concentration, it immunizes certain animals and may paralyze others."

In reply Dr. Park is quoted as saying: "Our virus may be living but it has been so reduced in activity that it never produces the disease when introduced into a patient. The child never becomes paralyzed. There is no question that Dr. Brodie gets immunity in the blood of the children he treats. Whether or not that is sufficient immunity we don't know."

Dr. Brodie is quoted as saying that he himself and about 10,000 children have received the vaccine and not one so treated has had infantile paralysis.

Onondaga County

THE PROBLEM now being attacked by Dr. George H. Whipple, of the College of Medicine of Rochester University, is to determine the manner in which the human body manufactures its red blood corpuscles. So he told 150 physicians at Syracuse on Oct. 17, at a joint meeting of the Rochester and Syracuse Academies of Medicine. His subject was "Problems of Anemia," and he revealed that in his work with Drs. Murphy and Minot which brought them the Nobel Prize, he did the laboratory work in California and Rochester while the others worked in the clinic in Boston. They kept each other posted on developments by correspondence.

Ontario County

DR. WALTER S. THOMAS, of Clifton Springs, was elected to head the Ontario County Medical Society at the annual meeting on Oct. 8th in Wenna Kenna tea room, east shore of Canandaigua Lake. He succeeds Dr. Albert M. Crane, of Geneva, who presided at the sessions.

In place of Dr. Thomas, Dr. C. W. Grove, of Geneva, was named vice-president, and Dr. D. A. Eiseline, of Shortsville, was elected secretary and treasurer for the 39th consecutive year. Members of the board of censors hold over until 1936, together with Dr. H. J. Knickerbocker, of Geneva, delegate to the annual convention of the State Medical Society next Spring. Dr. C. C. Lytle, of Geneva, was named alternate delegate in place of Dr. C. W. Selover, past president of the society, who died last July. About fifty attended the dinner and meeting.

Orange County

BECAUSE OF THE amazing growth in attendance at the free clinics at St. Luke's Hospital in Newburgh, physicians who have been donating their services have filed with the City and Town Home Commissioners a request that they receive compensation from public welfare funds at the rate of 50 cents per case. The hospital has also filed a request for compensation for X-rays taken in connection with the clinic.

Otsego County

GREATER COOPERATION between physicians and attorneys was urged by Willard Pratt, Utica attorney, at a joint meeting of the Otsego County Bar and Otsego County Medical associations at Hotel Oneonta on Oct. 16. Miss Marjory Murray of Coopers-town, president of the county medical association, represented that group at the speakers' table. Over one hundred attended.

Queens County

THE QUEENS COUNTY MEDICAL SOCIETY and the Queensboro Tuberculosis and Health Society learned from Hospital Commissioner S. S. Goldwater at a joint meeting a few weeks ago his plan to save New York city's 116 private hospitals from financial ruin. Under his plan, the labor unions would buy hospitalization either through annual contributions or through additional dues levied on their members. A similar plan has been successful in London.

THE QUEENS COUNTY Medical Society has pledged full cooperation in the proposed world's fair to be held in Queens in 1939, and has offered to "place its facilities at the Committee's disposal to co-ordinate other County Societies, the New York State Medical Society, The American Medical Association and the New York Academy of Medicine in planning exhibits pertaining to medicine and arranging for the reception and registration of visiting members of the profession."

Schenectady County

THE SCHENECTADY COUNTY MEDICAL SOCIETY observed the 125th anniversary of its founding on Oct. 12 with a dinner at the Mohawk Golf Club. Approximately 120 attended with members of societies from adjacent counties, the Schenectady County Dental Association, the Schenectady County Historical Society and several other distinguished persons present. Dr. Edward B. O'Keefe, president of the county medical group, presided and Dr. Dayton L. Kathan was toastmaster.

Interesting addresses were made by Dr. Dixon Ryan Fox, president of Union College, Dr. W. D. Coolidge, director of research at the General Electric Company, Dr. Francis C. Packard of Philadelphia, Dr. Ellis Kellert, Dr. Roy C. Keigher, and Dr. J. Eastman Sheehan.

The historical medical exhibit attracted great interest.

Seneca County

THE REGULAR ANNUAL MEETING of the Seneca County Medical Society took place at the Willard State Hospital, Willard, on October 10. Routine work occupied the morning, and after the luncheon Dr. John J. Lloyd of Rochester, N. Y., gave a talk with lantern slides on the "Treatment of Respiratory Diseases", and Dr. Ross E. Herold of the Willard State Hospital Staff gave a paper on the subject of "Melano Sarcoma in a Negro," followed by a series of unusual x-ray plates.

Warren County

FIFTY MEMBERS attended the annual banquet meeting of the Warren County Medical Society on Sept. 30 at Glens Falls. Officers were re-elected and an address was presented by Dr. Frederick E. Sondern of New York City, president of the Medical Society of the State of New York.

The officers re-elected are: President, Dr. Leonard A. Hulsebosch of Glens Falls; vice-president, Dr. George Bibby of Pottersville; secretary-treasurer, Dr. Morris Maslon of Glens Falls; board of censors, Dr. James B. Shields, Dr. B. J. Singleton and Dr. Herbert A. Bartholomew, all of Glens Falls; delegate to the Medical Society of the State of New York, Dr. Maslon; alternate delegate, Dr. H. E. Clarke.

Washington County

THE MEDICAL SOCIETY of the County of Washington, at its annual meeting at Hudson Falls on Oct. 1, elected these officers: President, E. V. Farrell; vice-president, J. H. Ring; secretary, S. J. Banker; treasurer, C. A. Prescott; board of censors, G. M. Casey, chairman, B. C. Tillotson, R. E. LaGrange; committee on legislation, W. A. Leonard, chairman; committee on public relations and medical economics, M. A. Rogers, chairman.

Papers of great interest were presented by Drs. French, Mezey and Stanton and by the President of the Society. Dinner was served at the Carleton Hotel. Twenty-nine members and visitors were present.

Westchester County

FOR THE FIFTH TIME in six years Yonkers has been given honorable mention in the National Health Contest conducted by the United States Chamber of Commerce as being one of the five cities between 100,000 and 500,000 population showing the greatest progress in health work. A plaque has been received by the department with a letter from the President of the Chamber of Commerce commending the work in Yonkers. Yonkers is rated among the first five cities in its population class in 1929, 1930, 1931 and 1932. It failed to qualify by a narrow margin in 1933 but has once more entered the qualifying group. The credit is generally accorded to the late Dr. Clarence W. Buckmaster, City Health Commissioner, who died on Oct. 7.

DR. CLAUDE W. MUNGER, Director of Grasslands Hospital, was elected President-Elect of the American Hospital Association at the recent annual convention of the association in St. Louis. Dr. Munger will take office as President in 1936.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Responsibility of Physician for Negligence of Another Physician

The responsibility of a physician and surgeon for negligent after care rendered a patient by another physician who takes over the case from the first physician was the subject of litigation which came before the Courts some time ago in one of the Western States.* The ruling is one which clearly determines the legal consequences in a situation which frequently arises in the everyday practice of medical practitioners.

The fact situation was a simple one. Mrs. H., who lived in a small town, was suffering from a certain abdominal ailment which required a surgical operation. She made the acquaintance of a medical student with whom she discussed her complaints, and he referred her to a surgeon in a nearby city, Dr. N. The medical student made arrangements with Dr. N. by telephone whereby the doctor was to come to a hospital located some distance from where he practiced, and perform the operation. This was done, and from all that appeared upon the trial of the case the operation was performed with complete success. Another surgeon of ability was present at the operation and was in a position to give testimony that it was in all respects skillfully performed. A physician interning at the hospital was also present at the operation. In finishing up the operation the surgeon found it necessary to leave a gauze drain in the incision, which of course was to be removed later. At the completion of the operation because Dr. N., the surgeon was unable to remain in the city where the hospital was situated, he made arrangements with the interne to look after the patient, dress the wound, and generally to care for her until she recovered. The interne assumed those duties but failed to remove the gauze drain at the proper time, according to the testimony. The surgeon never saw the patient after the operation.

An action was brought against the surgeon by the patient and her husband, charging him with malpractice on the theory that he was responsible for the negligence of the younger doctor who took over the case. Upon the trial there was no proof that Dr. N. made any arrangements with the interne whereby he, Dr. N., was to pay him for his services. There also was no proof that

Dr. N. was guilty of any negligence in the selection of the interne as a proper person to look after the patient, and to remove the gauze at the appropriate time. So far as appeared the interne was properly qualified to undertake all that he did in the case. Upon the trial the Court, over defendant's objection, instructed the jury that if Dr. N. employed the interne to take charge of the patient, for the purpose of dressing the wound, and removing the drain, and if the interne was guilty of negligence, the surgeon might be held liable, regardless of whether Dr. N. paid or undertook to pay him for his services.

There was a verdict in favor of the plaintiffs and the defendant took an appeal. The Appellate Court reversed the judgment of the trial Court. In support of its ruling reference was made to an earlier case where a similar situation had arisen. In that case a doctor had rendered temporary treatment for a dislocated arm, and having to leave the city, recommended that the patient go to another physician with whom he had made arrangements whereby the second doctor was to look after his patients in his absence. In that case it had been held that the first doctor could not be liable for the negligence of the second doctor, and the Court quoted from the opinion in that case as follows:

The employment of Dr. M. constituted an independent contract and Dr. K. is not responsible for his negligence or want of skill.

The Court drew a distinction in the situation from the ordinary relation of master and servant, citing the following:

A physician cannot be regarded as an agent or servant in the usual sense of the term, since he is not and necessarily cannot be directed in the diagnosing of diseases and injuries and prescribing treatment therefor, his office being to exercise his best skill and judgment in such matters without control from those by whom he is called or his fees are paid.

In determining to reverse the ruling of the lower Court, the Appellate Court said,

* * * it is clear that the instructions of the Court as to liability on the part of the defendant were erroneous. Appellant was not guilty of negligence in the performance of the operation, nor in the selection of a physician to continue the treatment after he left the city.

* Norton v. Hefner, 198 S. W. 97.

Not being negligent in those respects, he cannot be held responsible for the negligence of the other physician who was left in charge, merely because the other physician took charge on his suggestion and arrangement.

Reconstructive Operation on Knee

A young married woman came to a doctor specializing in orthopedic surgery, complaining of arthritis. On examination he found that she was suffering from ankylosis of the left knee, which had become permanently stiffened with bony infusum. He had an x-ray taken which confirmed his diagnosis. He suggested an operation for the purpose of attempting to improve the condition of her leg, to which she consented.

The doctor made a horse-shoe shaped incision under the patella, and then a straight incision from the middle down about three inches, cutting through deep fascia and the patella tendon, exposing the destroyed joint. He freed the patella from the femur and then with a chisel in the line of the new joint cut a V shaped line and removed enough bone to leave joint space. After this the doctor made an incision in the thigh and cut out a right angular piece of fascia and with this lined the opening for the new joint. He completed his operation and applied a cast.

The patient remained in the hospital and the doctor observed her condition daily. About five days after the operation he noticed that blood and serum was going through the gauze. He made a small opening through the cast in each side of the knee and dressed the wound and he continued his aftercare. Some time later he applied a Calliper knee brace. At about that time he undertook to bend the knee by manipulation but the patient did not cooperate and he was unable to get much motion.

The patient remained in the hospital about two months in all and when she left she was walking with a crutch and the brace. She returned to the doctor's office several times over a period of two additional months and on each of those occasions the doctor tried to limber up the stiff knee. The woman was a hysterical type of patient and would not cooperate, claiming that the pain was too great to permit manipulation of the limb.

When the doctor last saw her the wounds occasioned by the operation had fully healed but her knee was still stiffened. She was able to walk without a brace or crutch but she had very little actual improvement in her condition.

She subsequently brought an action against the doctor charging him with alleged malpractice, making the further claim that

subsequent to the operation he had violently assaulted her; said claim apparently being based on his attempts to manipulate the limb.

After the case had been dormant for some time a motion was made to dismiss the case for lack of prosecution and the plaintiff's attorney obtained permission from the court upon the argument of that motion to restore the case for an early trial. He failed to do so, however, and upon a subsequent application made on behalf of the defendant the case was finally dismissed.

Confusion of Prescriptions

A general practitioner was called to the home of a child about a year old and found him in bed suffering from otitis media and upper respiratory infection. In the course of his treatment he gave the patient two prescriptions to be filled, one calling for "Tincture Opil and Olive Oil—2 drams of each—instructions: 2 to 3 drops in ear two or three times a day"; and the other one, calling for "Elixir Luminol, 20 drops, 3 times a day internally." Subsequently thereto the child developed pneumonia and was taken to a hospital where he remained for about ten days under the care of another doctor and returned home in good condition and apparently cured. From what the doctor learned later it appeared that when the two prescriptions were taken to a druggist, the druggist compounded them properly but confused the labels so that the medicines were delivered to the parents of the child with instruction that the ear drops were to be taken internally and that the internal medicine was to be used as ear drops. Precisely what, if any, damages the druggist's mistake caused the child was impossible to ascertain.

An action was brought against the doctor and the druggist as co-defendants, charging them both with responsibility for the confusion of the prescriptions. A check up of the prescriptions showed that the doctor had made no mistake in writing them up. When the case was about to be reached for trial the plaintiff's attorney arranged with the attorney for the druggist to settle the case for a small sum and at the same time he made efforts to obtain an additional settlement of the matter from the doctor. Since the doctor insisted that he had made no mistake in the case no offer was made to contribute to the settlement on his behalf and finally the plaintiff's attorney consented to discontinue the matter as to the doctor, contenting himself with the small settlement which he had received from the druggist, thereby admitting he had no basis for his complaint against the doctor.

Responsibility of Physician for Negligence of Another Physician

The responsibility of a physician and surgeon for negligent after care rendered a patient by another physician who takes over the case from the first physician was the subject of litigation which came before the Courts some time ago in one of the Western States.* The ruling is one which clearly determines the legal consequences in a situation which frequently arises in the everyday practice of medical practitioners.

The fact situation was a simple one. Mrs. H., who lived in a small town, was suffering from a certain abdominal ailment which required a surgical operation. She made the acquaintance of a medical student with whom she discussed her complaints, and he referred her to a surgeon in a nearby city, Dr. N. The medical student made arrangements with Dr. N. by telephone whereby the doctor was to come to a hospital located some distance from where he practiced, and perform the operation. This was done, and from all that appeared upon the trial of the case the operation was performed with complete success. Another surgeon of ability was present at the operation and was in a position to give testimony that it was in all respects skillfully performed. A physician interning at the hospital was also present at the operation. In finishing up the operation the surgeon found it necessary to leave a gauze drain in the incision, which of course was to be removed later. At the completion of the operation because Dr. N., the surgeon was unable to remain in the city where the hospital was situated, he made arrangements with the interne to look after the patient, dress the wound, and generally to care for her until she recovered. The interne assumed those duties but failed to remove the gauze drain at the proper time, according to the testimony. The surgeon never saw the patient after the operation.

An action was brought against the surgeon by the patient and her husband, charging him with malpractice on the theory that he was responsible for the negligence of the younger doctor who took over the case. Upon the trial there was no proof that Dr. N. made any arrangements with the interne whereby he, Dr. N., was to pay him for his services. There also was no proof that

Dr. N. was guilty of any negligence in the selection of the interne as a proper person to look after the patient, and to remove the gauze at the appropriate time. So far as appeared the interne was properly qualified to undertake all that he did in the case. Upon the trial the Court, over defendant's objection, instructed the jury that if Dr. N. employed the interne to take charge of the patient, for the purpose of dressing the wound, and removing the drain, and if the interne was guilty of negligence, the surgeon might be held liable, regardless of whether Dr. N. paid or undertook to pay him for his services.

There was a verdict in favor of the plaintiffs and the defendant took an appeal: The Appellate Court reversed the judgment of the trial Court. In support of its ruling reference was made to an earlier case where a similar situation had arisen. In that case a doctor had rendered temporary treatment for a dislocated arm, and having to leave the city, recommended that the patient go to another physician with whom he had made arrangements whereby the second doctor was to look after his patients in his absence. In that case it had been held that the first doctor could not be liable for the negligence of the second doctor, and the Court quoted from the opinion in that case as follows:

The employment of Dr. M. constituted an independent contract and Dr. K. is not responsible for his negligence or want of skill.

The Court drew a distinction in the situation from the ordinary relation of master and servant, citing the following:

A physician cannot be regarded as an agent or servant in the usual sense of the term, since he is not and necessarily cannot be directed in the diagnosing of diseases and injuries and prescribing treatment therefor, his office being to exercise his best skill and judgment in such matters without control from those by whom he is called or his fees are paid.

In determining to reverse the ruling of the lower Court, the Appellate Court said,

* * * it is clear that the instructions of the Court as to liability on the part of the defendant were erroneous. Appellant was not guilty of negligence in the performance of the operation, nor in the selection of a physician to continue the treatment after he left the city.

* Norton v. Hefner, 198 S. W. 97.

A GOOD OLD FAMILY DOCTOR who went to his reward the other day had never used an automobile, but held loyally to the faithful horse and buggy. Perhaps he was antiquated, but as he jogged along he had time to give thought to his medical problems as he could not do if he were roaring away at sixty or sixty-five. A country doctor recently remarked: "I am not as good a doctor as I was in the horse and buggy days. Then, I had time to think of my last patient before getting to the next. Now sometimes I slow my car down to fifteen or twenty miles, trying to think, and, damme, I am forced off the road or honked at by others until I get mad. Then I drive like hell, just like the rest!"

WHY NOT MAKE a slight change in a familiar slogan and hang a new motto on the Christmas tree, reading "Safe-toy First." Loving parents who give their children air-rifles, motorcycles, toy swords and sharp instruments of all sorts sometimes blame heaven for the resulting accidents that blind, maim, or kill them. The National Safety Council reports that from the time children begin to walk alone more of them die from accidents than from any disease, and between the ages of three and eighteen, "no disease even approaches accidents in virulence." Physicians giving health talks may well include a paragraph on safe toys and safe play.

Making War Healthier

A "MEDICAL MIRACLE" is reported by the medical department of the Italian Army. The losses from sickness are said to be amazingly low. Vast provisions of medical and hospital supplies, with doctors and nurses, accompany the troops; the men receive injections against typhoid, paratyphoid and cholera; quinine is given regularly, and infected water areas are covered with petroleum.

This is strictly in line with the improvement shown in the figures for modern and former wars. Take a similar campaign of a century ago, when France sent an army of 58,000 to Santo Domingo, and 50,000 died of disease, or 86.2 per cent. The advance of medical science has made anything like that impossible today. In the

British campaign in South Africa in 1899-1902 only 3.6 per cent of the troops died of disease; in our Spanish-American War only 1.7 per cent of our men died of disease, and in the World War, despite the flu and pneumonia epidemic, the percentage in our forces was only 1.4.

In modern armies, in fact, many of the men have better food and clothing and better medical and dental care than they had at home, and their military service adds years to their lives, so that while war takes life with one hand, it gives with the other. And the credit side of the ledger is due entirely to the men of medical science.

A State Slipping Backward

IT IS AN AMAZING fact that while Mussolini's men are receiving injections to protect them from typhoid and cholera, one of our Pacific Coast states is suffering from a scourge of smallpox due entirely to popular hostility or indifference to vaccination. One-fifth of all smallpox cases in the United States in the first nine months of this year occurred in the State of Washington. The exact number was 1,014, or 1,014 more than necessary. Contrast Washington, and its 1,400,000 population, with an eastern city of 800,000 which has not had a single case of smallpox in six years, and you get the picture.

A medical journal in Seattle reports that the doctors encounter a stubborn hostility to vaccination among certain sects and cults, and a cold indifference in the general population which is hard to overcome. The situation has been growing worse for several years, with 288 smallpox cases reported in 1933, 580 in 1934, and 1,014 in nine months of 1935. Physicians, health officers, nurses, and public officials are now aroused to a vigorous campaign in which these figures will be used to drive the lesson home. And they can be just as useful in our own towns and cities to show what may happen if we relax our vigilance.

MENTAL EXAMINATIONS of automobile drivers, to eliminate the morons, is urged by a committee of the New York Academy of Medicine. True, that might have its advantages, but driving in solitude on the deserted roads would be rather lonely.

MEDICAL RADIO BROADCASTS

Dr. Morris Fishbein, editor of the *J.A.M.A.*, will speak on "Tuberculosis" on December 3, and on "Hunting Accidents" on December 10 in the series of broadcasts

of the American Medical Association on the National Broadcasting Company's blue network. The addresses are on Tuesdays, at 5 P.M. eastern standard time.

RECEIVED

[Acknowledgment of all books received by the JOURNAL will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Individual Exercises Selected Exercises for Individual Conditions. By George T. Stafford, M.S., Harry B. DeCook, M.A. and Joseph L. Picard, M.S. Octavo of 111 pages, illustrated. New York, A. S. Barnes & Company. 1935. Paper, \$1.00.

Modern Home Medical Adviser. Your health and how to preserve it. Edited by Morris Fishbein, M.D. Quarto of 905 pages, illustrated. Garden City, Doubleday, Doran & Company. 1935. Cloth, \$9.50.

Diseases of the Thyroid Gland. By Arthur E. Hertzler, M.D. Third edition. Octavo of 348 pages, illustrated. St. Louis, The C. V. Mosby Company. 1935. Cloth, \$7.50.

A Textbook of Laboratory Diagnosis. With Clinical Applications for Practitioners and Students. By Edwin E. Osgood, M.D. Second edition. Octavo of 585 pages, illustrated. Philadelphia, P. Blakiston's Son & Co. 1935. Cloth, \$6.00.

REVIEWED

(For other reviews see pages 1189 and 1218)

Stammering and Allied Disorders. By C. S. Bluemel, M.D. Duodecimo of 182 pages. New York, Macmillan Co., 1935. Cloth, \$2.00.

The author presents a new theory of stammering based on the conditioned reflex in inhibition. There is a general description of the conditioned reflex. Speaking, reading, and writing are conditioned responses, being symbols which a child learns but does not inherit. Inhibition is a physiological stimulus which checks the conditioned reflex. The conflict between the conditioned reflex and the shock which produces the inhibition of the reflex may result in a great emotional upset.

There has long been recognized a relationship between shock and stammering. At first mutism occurs and then when speech is regained there is stammering. The stammering speech following mutism means that the inhibition has only been partial. The author denotes this as primary stammering and states that it is particularly noticeable in children because the conditioned reflex of speech is not fully established in childhood. The etiological factor he labels a conditioned or associative inhibition. In the secondary stage the patient becomes emotionally conditioned to words or persons and thus stammers all the more. He may develop symptoms such as abnormal respiration during speech, show great physical effort and frequently resort to synonyms to avoid the word to which he is conditioned. Males stammer four times more than females probably because they do not have as great a facility of speech.

Other theories for stammering such as visualization, handedness, and conflict are explained and then discarded by the author.

The treatment consists of rest, tranquilization, sedatives, and reinforcement of the

reflex unconditioning. The prognosis is good in primary stammering if treatment is begun early, but it is poor in the secondary type.

While one may not agree entirely with the viewpoint presented here, the reviewer feels that the book is of great value as it does attempt to explain the cause of stammering in broader concepts. It is also of help because of its optimistic point of view. The reviewer recommends it to the profession.

STANLEY S. LAMM

The Physical and Mental Growth of Prematurely Born Children. By Julius H. Hess, M.D. et al. Octavo of 449 pages. Chicago, University of Chicago Press, [c. 1934]. Cloth, \$5.00.

This book is divided into three parts. The first is a clinical study, the second is concerned with developmental studies of premature born children, and the third deals with special studies carried out in the premature infant station. The material studied includes 1,623 prematures either born in the Michael Reese Hospital or brought to it from a home or another hospital. The mortality of the transported group is higher. However, due to stress being placed on the maintenance of a normal temperature and the avoidance of chilling after birth and during transportation this mortality has been reduced from 53 per cent in the early years to 24.5 per cent in the group studied between 1930 to 1933. Multiple pregnancy was the most common single cause of premature labor. The next precipitating factor was toxemia of pregnancy. In the next group were syphilis and tuberculosis followed by such other factors as acute infections, systemic disease, and local conditions as placenta previa.

In their conclusions with respect to the

development of prematures the authors state that the premature group are able to sit unsupported at as early an age as the sibling group, but are slightly delayed in walking. The earliest developmental habits and feeding show no difference. Similarly for teething. The onset of speech is similar but stuttering was noticed more frequently in the prematures.

There are special subjects studies with reference to the premature group such as a survey of the infants surviving a weight of less than a thousand grams, intracranial hemorrhage, and other topics.

The authors have attempted to answer such questions as the ultimate outlook for prematures, the comparison of morbidity and mortality in early childhood between prematures and those born full time, and finally the physical and mental status of those prematures who survive. The data is well arranged through a profuse use of charts and tables. It is a comprehensive survey of prematurity, and should be of interest to the profession.

STANLEY S. LAMM

A Brief Outline of Modern Treatment of Fractures. By H. Waldo Spiers, M.D. Octavo of 129 pages, illustrated. Baltimore, William Wood & Co., 1935. Cloth, \$2.00.

This little book of 125 pages is just what its title implies. It is well arranged into 13 chapters, each dealing with one type of fracture. The script is, of necessity, brief on each phase of fracture work but it is complete enough to give a good general idea of the procedure described.

The work should be in the hands of each intern on a given fracture service and it would be a fine handbook for nurses who are in care of such cases. As a ready reference work for the general practitioner it will find a wide field of usefulness in helping him to treat the fracture patient in the most modern manner and it will guide him away from some of the old, and pernicious, methods which lead to future trouble for the patient and surgeon if the case becomes hospitalized.

H. WRIGHT BENOIT

Industrial Medicine. By W. Irving Clark, M.D. & Philip Drinker, S.B. Edited by Morris Fishbein, M.D. Duodecimo of 262 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

This monograph on Industrial Medicine, is a most valuable and welcome contribution. Dr. W. Irving Clark and Dr. Philip Drinker are both known for their outstanding work in Industrial Medicine.

The first chapter on Industrial Medicine Department, will be found to be of great interest by those interested in the subject

and particularly by the medical directors of industrial plants.

The first four chapters of the book are given over to discussion of general matters in relation to industrial medicine, which will interest every practitioner who works in an industrial community.

The authors then go on to discuss the subjects of Pneumoconiosis, Lead Poisoning, Metal Fume Fever, Industrial Dermatoses, Gases, Benzol, Asphyxia and Artificial Respiration.

In the last chapters, they discuss the Prevention of Industrial Diseases.

The book is illustrated sufficiently to bring to the attention of the reader the important differential points in diagnosis, especially so in the chapters on Pneumoconiosis.

The Bibliography is excellent and completes a splendid monograph on the subject of Industrial Medicine.

IRVING GRAY

Obstetrics for the General Practitioner. By J. P. Greenhill, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 304 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

A small handy size volume devoted to the practical aspects of obstetrics. Written for the general practitioner it is simple, plain and to the point. No space is wasted on academic discussion with which the average man is not concerned. Descriptions of operative shortcuts are missing. A boiled down DeLee, it reflects the personal experience of Greenhill, who is always very practical. A remarkably good book which should serve its purpose well. The reviewer has never seen a better one.

CHARLES A. GORDON

A Manual of Obstetrical and Gynaecological Pathology. By John H. Teacher, M.D. Octavo of 407 pages, illustrated. New York, Oxford University Press, 1935. Cloth, \$15.25.

Professor Teacher realized the dire need of a comprehensive manual in English, covering all phases of obstetrical and gynecological pathology; but unfortunately during the process of writing the book Dr. Teacher died before he had completed it. The unfinished portion, however, has been written by a well known group of men and women who are well versed in the pathology of obstetrics and gynecology.

The result is this manual, which is by far the best book of its kind in the English language. In it all phases of obstetrical and gynecological pathology are thoroughly reviewed. The chapters on diseases of the endometrium, the early development of the ovum, and malignant tumors of the uterus are the most outstanding chapters in the book for their completeness.

The book is profusely illustrated with excellent photographs of both gross material and microscopic sections. The few colored plates in the book are excellently reproduced.

This book is a welcome addition to the literature and is highly recommended to all men interested in obstetrics and gynecology.

MORRIS GLASS

Diseases of Children. Third edition with contributions by 36 authors, edited by Hugh Thursfield, D.M., and Donald Paterson, M.D. First edition by Sir A. E. Garrod, D.M., the late Frederick E. Batten, M.D., and Hugh Thursfield, D.M. Octavo of 1152 pages. Baltimore, William Wood & Co., 1934, Cloth, \$10.00.

This edition of Garrod, Batten and Thursfield, edited by Thursfield and Paterson maintains its position as probably the best written pediatric text book in the English language. The facts are always interestingly presented for they are not hitched end to end in the almanac style so characteristic of medical text books. The material covered is enormous, so that even the most rare conditions are comprehensively discussed. The chapters on nervous conditions are especially fine.

These authors have the knack of presenting the extraordinary and critical points which must usually be unearthed in large systems or in a multitude of periodicals. A noticeable departure which will please American pediatricists is the somewhat belated recognition accorded the many excellent American and other foreign pediatric researches in the splendid bibliographies appended to each section. The recommendations for treatment are unusually clear and useful in a practical way.

All in all, we believe this to be the best single volume reference book in pediatrics.

CHARLES A. WEYMULLER

Diabetic Manual for Patients. By Henry J. John, M.D. Second Edition. Duodecimo of 232 pages. St. Louis, C. V. Mosby, 1934. Cloth, \$2.00.

The chief changes in this second edition consist in liberalizing the diets. These prescribe more fat and less carbohydrate per calorie than customary in recent times.

The cause and definition of Diabetes Mellitus is arbitrarily given as due to the pancreatic islands alone. No mention of extra pancreatic causes for Diabetes Mellitus is made.

The dramatic comparison of the effects of the pre to post insulin therapy is capably presented. The more that diabetics learn to know their abnormal physiology through such books as this, the longer and better lives they will have.

DAVID GLUSKER

The Management of Colitis. By J. Arnold Barga, M.D. Edited by Morris Fishbein, M.D. Duodecimo of 234 pages, illustrated. New York, National Medical Book Company, Inc., 1935. Cloth, \$4.00.

Half of the volume of 225 pages deals with the research work previously published from the Mayo Clinic on Chronic Ulcerative Colitis. The supposed etiological agent, the diplo-streptococcus of Ulcerative Colitis, is emphasized, and the history, pathology, diagnosis, complications and treatment, are discussed from this angle.

Amebic, tuberculous, and so called Mucous Colitis, are presented in detail. Bacillary Dysentery is barely mentioned, although the general practitioner would certainly welcome guidance in the management of this disease.

WILLIAM Z. FRADKIN

A Diabetic Manual for the Mutual Use of Doctor and Patient. By Elliott P. Joslin, M.D. Fifth Edition. Octavo of 224 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$2.00.

Doctor Joslin is the veteran writer of manuals for the diabetic. His first manual was the progenitor of many that have been written by other hands, and his latest one surpasses all of his previous ones. He has never swerved from his original purpose of writing a manual for the education and instruction of the patient, and while it would serve the physician the point of view was taken entirely with the patient himself as a guide; his needs of fact, symptoms, and details of taking over the management of his life. The latest member of his family of manuals, gives more of hope and enthusiasm, more of actual fact, (for the diabetic children of his early books have grown and married) than any of the earlier ones, and consequently they become the examples of what he wants to say, and impress the diabetic with the fact that diet and insulin and care enable him to go on very much as any other individual except for his regime. As to this it also here is drawn with greater freedom than formerly, so that the diabetic can carry on as well with very much less of irksome detail of diet and arithmetic. In this manual are included very much more definite words as to the relation of the diabetic and marriage, and also the factor of heredity, which are based on later studies. There is no doubt but that if the diabetic is given the choice, he would choose this manual, and the physician will find in it, all of the facts he needs to properly lead his patients in the safest way for them to travel.

LOUIS C. JOHNSON

GENETICS AND CLINICAL MEDICINEGEORGE DRAPER, M.D., *New York City*

In a previous paper¹ emphasis was laid upon the school of biological thought which considers the organism to be greater than its parts, and the effort was made to bring this attitude into relation with clinical medicine. It was shown that the physician was faced with the difficult task of knowing the total individuality of the man within the patient, or, as Samuel Butler² phrased it, "his personal identity."

Butler's remarks on the subject of personal identity in relation to heredity and the organismal concept are so excellent that I shall quote in full the passage which deals with it:

For surely all reasonable people will feel that an infant an hour before birth, when in the eye of the law he has no existence and could not be called a peer for another sixty minutes, though his father was a peer and already dead—surely such an embryo is more personally identical with the baby into which he develops within an hour's time than the born baby is so with itself (if the expression may be pardoned) one, twenty, or it may be eighty years after birth. There is more sameness of matter; there are fewer differences of any kind perceptible by a third person; there is more sense of continuity on the part of the person himself, and far more of all that goes to make up our sense of sameness of personality between an embryo an hour before birth and the child on being born than there is between the child just born and the man of twenty. Yet there is no hesitation about admitting sameness of personality between these last two.

On the other hand, if that hazy contradiction in terms "personal identity" be once allowed to retreat behind the threshold of the womb, it has eluded us once for all. What is true of one hour before birth is true of two, and so on till we get back to

the impregnate ovum, which may fairly claim to have been personally identical with the man of eighty into which it ultimately developed, in spite of the fact that there is no particle of same matter nor sense of continuity between them, nor recognized community of instinct, nor indeed of anything which goes to the making up of that which we call identity.

There is far more of all these things common to the impregnate ovum and the ovum immediately before impregnation or again between the impregnate ovum, and both the ovum before impregnation and the spermatozoon, which impregnated it. Nor, if we admit personal identity between the ovum and the octogenarian, is there any sufficient reason why we should not admit it between the impregnate ovum and the two factors of which it is composed, which two factors are but offshoots from two distinct personalities, of which they are as much part as the apple is of the apple-tree; so that an impregnate ovum cannot without a violation of first principles be debarred from claiming personal identity with both its parents, and hence, by an easy chain of reasoning, with each of the impregnate ova from which its parents were developed.

So that each ovum when impregnate should be considered not as descended from its ancestors, but as being a continuation of the personality of every ovum in the chain of its ancestry, which every ovum *it actually* is quite as truly as the octogenarian is the same identity with the ovum from which he has been developed.

This progress cannot stop short of the primordial cell, which again will probably turn out to be but a brief resting place. We therefore prove each one of us to be *actually* the primordial cell which never died nor dies, but had differentiated itself into the life of the world, all living beings whatever, being one with it and members one of another.

*From the College of Physicians and Surgeons, Columbia University, and
the Presbyterian Hospital*

F. Mother

(1) F. Father

Died at 80 years. Capable, dominating woman, maintained the position as head of the family. Managed business successfully.

Died at 60 years. Delirium tremens. Chronic alcoholism. Owned small country store. Unsuccessful. Wife managed business and family.

(2) F. Brother

Lived to 60 years. Athletic build. Health good. Wealthy successful merchant in Dublin. Dominant personality. Hobbies: fishing and hunting. Married. Two children.

F. Brother

Died in early 30's of tuberculosis. Medium build. Managed country store. Not married.

F. Sister

Died in early 30's of tuberculosis. Short, slender. "Lived for and with mother. Fear of going out alone. Few social contacts. No men friends.

Pl's Father

Living, 57 years. Medium height; slender; sharp, finely chisled features. Health good.

Voice teacher with high standing. Poor financial provider. Completely absorbed by work, 8 a.m.—10 p.m. Gave up teaching 7 years ago. Temperamental maladjustment. Now runs small country store. Wife's conditions precipitated change. Violent temper. Married at 18 years. Little interest in family.

Pl's Mother

Living, 56 years. Short, stout. Delirium tremens in 30's. Excessive drinking from 30-48 years.

Woman of marked social charm and grace. Maladjustment in home led to alcoholism. Has begun several business ventures in interior or decorating. Personal habits cause failure. Excellent music and artistic. "Peculiarly sweet and tender person." Married at 17 years. No drinking after birth of last child.

Two Brothers,

One Sister
Died at 40-50 years of age. No further information.

M. Brother

Farmer in Michigan. Not married.

M. Sister

Quiet retiring. Married; several children. No further information.

(3)

Sister

Medium height; slender. Health good.

Took mother's place in the family. Dominating, critical. Married at 20 years to a physician. Adaptation poor. Extravagant, selfish. Two children. Little attention or apparent interest in children.

Patient

Medium height; slender. Acute rheumatic fever at 15 years. Duodenal ulcer. (See personal study.)

Sister

Medium height; slender. Club feet—operative treatment. Health good.

Quick tempered, erratic, indecisive. Only member of family who defied father during his temper tantrums. Came to America at 30. Married shortly afterward to ship acquaintance. First male friendship, unhappy marriage—history of frequent separation with impending divorce. Three children.

Sister

Short; slender. Long history of chronic eczema during childhood. Quiet, gentle, sensitive. Usually cried during family quarrels. Married at 23 to a physician. Three children. Constant friction. Mcneely distribution and his attention to other women. Divorced. She now manages a hotel and is a successful executive.

Sister

Medium height; slender. Chronic constipation. Indigestion—care in selection of food controls this. Living, 23 years.

Critical, argumentative, self-assertive. Has set ideas. Selfish determination to lead her own life. Ambitious. Holds good social position. Maintains her own apartment. Many men friends though she scoffs at marriage in view of the maltreatment of her parents and sisters.

can be

Fig. 1. Showing amount of information about numerous members of a family which can be obtained by painstaking interviews with as many individuals in the clan as possible.

Illustration by courtesy of Archives of Internal Medicine from *The Man-Environment Unit and Peptic Ulcer* by Draper and Touraine.

Perusal of the foregoing statement indicates that should one attempt to make a detailed investigation of the elusive quality which is called "individual constitution" by modern workers, and "personal identity" by Butler, one is forced to consider three stages at the outset of a person's life. These are all intimately involved in the production of the completed individual (phenotype) who as patient confronts the physician.

The first state of the individual is that of the fertilized egg—the microscopic treasury of a complete genetic history. From the organismal standpoint, Conklin³ emphasizes the significance of this tiny unit by the statement that "from its earliest to its latest stage an individual is one and the same organism, the egg of a frog is a frog in an early stage of development." The second and third stages are those respectively of the developing embryo and the infant years. These epochs will be dealt with in subsequent articles.

Further consideration of the first stage leads naturally to the study of a human being's heredity and brings up the whole difficult problem of clinical genetics. There are some who feel that very little value can be attached to anyone's account of his forebears. Few of us can recall much detail of the lives of even our grandparents. For this reason Siemens⁴ tries chiefly to get information about collateral branches of the patient's family. We have not limited our investigations in this way however, believing that every now and then most valuable and dependable information about ancestors can be found. In general our genetic studies have embraced the following points: racial extraction, morphologic types, disease history, sex distribution and in a few disease groups also the psychologic pattern. In taking the family disease and psychological histories one must beware of the patient's tendency to project his own symptoms and attitudes of mind upon other members of the clan. For this reason it is desirable to interview as many other persons in the family as possible. An example of the form in which a family history, designed to display personal identity or constitution pattern, may be conveniently arranged as shown in the plan⁵ on the facing page (Fig 1).

CASE I* A woman physician of Russian Jewish extraction, suffered from migraine, myopia, hypertension, nephritis, and at the time of the examination was passing through the menopause. In the past she had had mild rheumatism, arthritis, and asthma. She was also the mother of a feeble minded child and this circumstance coupled with the pathological states which she observed in her ancestry, had stimulated her interest in securing an account of her forebears and collaterals which was as accurate and detailed as possible. It might be remarked in passing that the discomforts of her own illness were not rendered easier by the knowledge of the special tissue fault which caused the death of so many of her relatives. Indeed, she had resigned herself to the belief that she would die from the same cause to which many of them had succumbed. The genetic history shows a marked weakness of the cardiovascular system (Fig 2). The patient's mother, two of the patient's mother's brothers, and three of her sisters had died of cerebral hemorrhages, all having died at the third attack. The patient's maternal grandmother died of her second cerebral hemorrhage. More remote family history was not available. A brother and a sister of the patient's mother died when forty-five years old of cardiac diseases. The patient's only brother has the history of a heart lesion, angina pectoris, asthma, and syphilis, the treatment of which in 1927 caused salvarsan poisoning. There are four known cases of rheumatic heart disease in the maternal line of this family and one case of nephritis and hypertension aside from the one already referred to above. There is, likewise, one case of diabetic gangrene. It was not possible to get histories of all the relatives, due to the fact that they were in Europe, and there is little contact between the two families. The patient's mother had severe myopia and at the time of her death, at the age of sixty, was practically blind. No other member of this family, except the patient, is known to have had any eye trouble, and none have worn glasses. Both

* Cases I and II and the studies on inguinal hernia and acute rheumatic fever are quoted almost verbatim from the article entitled *Studies in Human Constitution VI Clinical Genetics* which appeared in *J. A. M. A.* Vol. 92, page 2149, 1929. This material has been used again because it falls naturally into place in the present more complete discussion.

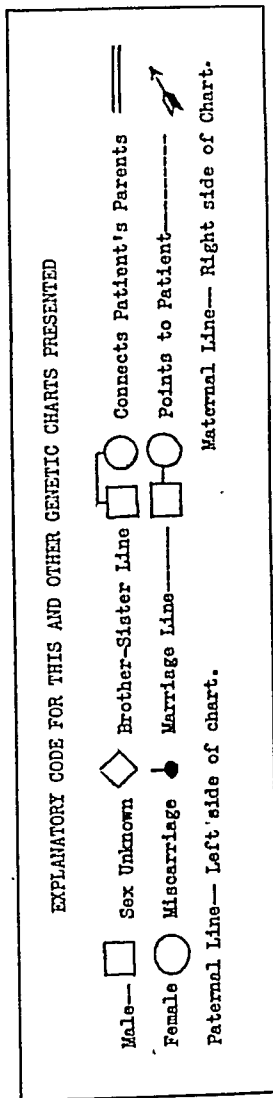

Fig. 2. Family Tree of Patient. Case I.

the patient's father and mother had migraine, but no other cases are reported in the family. The patient's brother has a microcephalic idiot child. Since the birth of the child, he has had a normal child by a different wife. Last year he found that he had syphilis but does not know for how long he was affected. The patient's youngest child is mentally retarded but apparently not to a marked extent.

This case also illustrates in an interesting way the effect which the thought of her anticipated end exerted upon the woman's total personality. Not only did her tissues contain the menacing heredity, but the knowledge of it became a destructive factor in her adult psychological environment. It colored her whole life, which is to say, herself, and evidently contributed to the impression of eager intense concentration and alertness which emanated from her.

CASE II The second study presents the case of a young woman thirty years of age. Diagnosis: acute rheumatic fever with heart involvement, mitral insufficiency. The patient is tall and slender with narrow face, blue eyes and light blond hair, and well represents a mixture of northern progenitors which includes, on the paternal side, German Lithuanian, Norwegian, Swedish and Scotch elements, on the maternal side, Scotch, English and German. Furthermore, the parents of the patient were distant cousins and there have been at least five other intermarriages between the two families at other points across the five generations recorded. The patient is a highly trained worker in various fields of biological technique related to medicine. Consequently she is familiar with medical terminology and the symptoms of disease. Her intelligence is of a high order and the measure of her general culture is perhaps best indicated by her command of at least four languages besides English (Fig. 3).

In this remarkably complete history, there is reliable and detailed information about every member of the family for the past three generations. Concerning those in the direct line, the facts are practically complete for five generations. The number of individuals in the first two generations about whom anything is known is more limited than in later ones,

but everything which is reported about these remote members of the clan is correct.

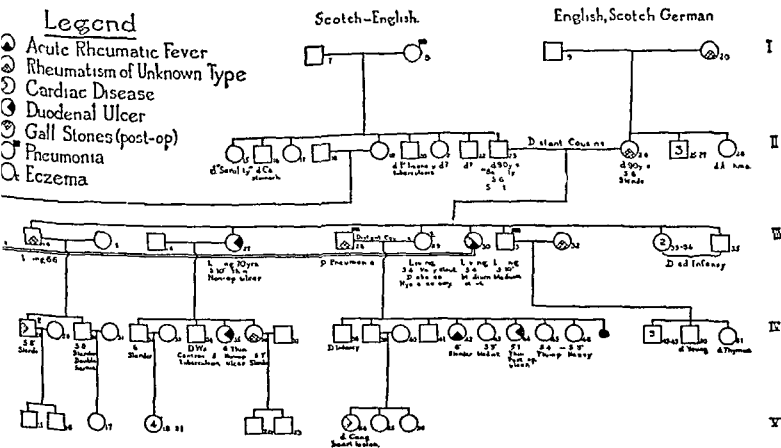

The outstanding quality of disease susceptibility in both sides of the patient's family appears to be the capacity of the members to develop rheumatism with cardiac sequelae. There is besides an obvious lack of resistance to pneumonia, which appears regularly for five generations in the direct line on the father's side. While this pulmonary inadequacy is not so intensively developed in this family as in the Hinking Nowhied family reported by Pearl⁶ still its occurrence is so constant as to merit consideration from a constitutional standpoint. Duodenal ulcer also was a disease which the patient developed and there are three other cases with this condition on the maternal side. Curiously enough, all these duodenal ulcers occurred in women, a circumstance which is quite foreign to our experience. Furthermore, these duodenally affected females were slender, delicate and essentially feminine types. This likewise does not accord with our experience that it is the more masculine type of women who develop ulcer. In addition to the patient's own rheumatic fever, heart disease and pneumonia she is extremely sensitive to skin eruptions and urticaria. In this connection, it is interesting to observe the scattered cases of eczema and hives which appear in the chart. So far as physical habitus is concerned, practically every member of the entire family is of the marked linear type, many indeed being well above the average height. In the fifth generation of the family there are several instances of congenital anomaly, two heart lesions and one case of undescended testis and inguinal hernia.

The living conditions in which this whole family has developed have always been of the very best. Many of the members have followed the highest types of professional careers and in some instances there has been more than average wealth. The patient's mother was an extremely nervous woman who was continually emphasizing the importance of disease prevention to her children. She was evidently oversolicitous in respect of her children's health because the patient remembers vividly, as the outstanding episodes of her early childhood and ado-

valuable the genetic survey can be in helping us to understand the woman within the patient, they do not clearly reveal a mechanism of heredity. Yet it is among unusually complete family records of this sort that one occasionally encounters an almost perfectly worked out genetic experiment. The reader is referred to Fig 16 for an example of such a case. There is a great difference, however, between the point of view of the experimental geneticist and that of the family doctor who seeks all the information he can about his patient's forebears and siblings. The experimentalist determines the conditions and selection of crosses in the animals he employs and then observes the results. Upon these he builds explanatory hypotheses and may fall upon the danger of creating biological entities by the use of names, as for example, the "determinants" of Weissmann and the "genes" of Johannsen and of Morgan. In fairness to the latter two observers, however, it should be said that they are more interested in a dynamic or chemicobiological concept than in a strictly morphological or topographic one. The physician, on the other hand, can witness only the results of accidental or naturally selected matings. From these he tries to draw some help in the difficult task of judging the per-

sonal identity of the patient, and some idea of the latter's disease potentiality. Yet it is also true that from certain observations on human heredity in the clinic some of the laboratory demonstrations of genetic mechanism such as that of hemophilia, were very accurately foretold.

But those other aspects of clinical genetics recounted under Cases I and II deserve the utmost consideration for they are of immediate value to the physician. The stranger one meets, or the new patient, appears at first as a detached specimen. One sees him, as it were, isolated in space, in a colorless setting. If, however, the family members can be sketched in, in greater or less detail, one then sees the person against a background into which he fits and from which he seems to draw illumination. Furthermore, just as we know that conduct or behavior resemblances, as well as physical, "run in families" so we know of various pathological states which do likewise. The twinning or doubling tendency already referred to has been thoroughly studied by Ashner in J. Bauer's clinic. In addition, a number of other inherited developmental faults in structure have been described, as, for example, hammer toe, hare lip, cleft palate, congenital cataract, etc. From our collection, the following

GEORGE DRAPER

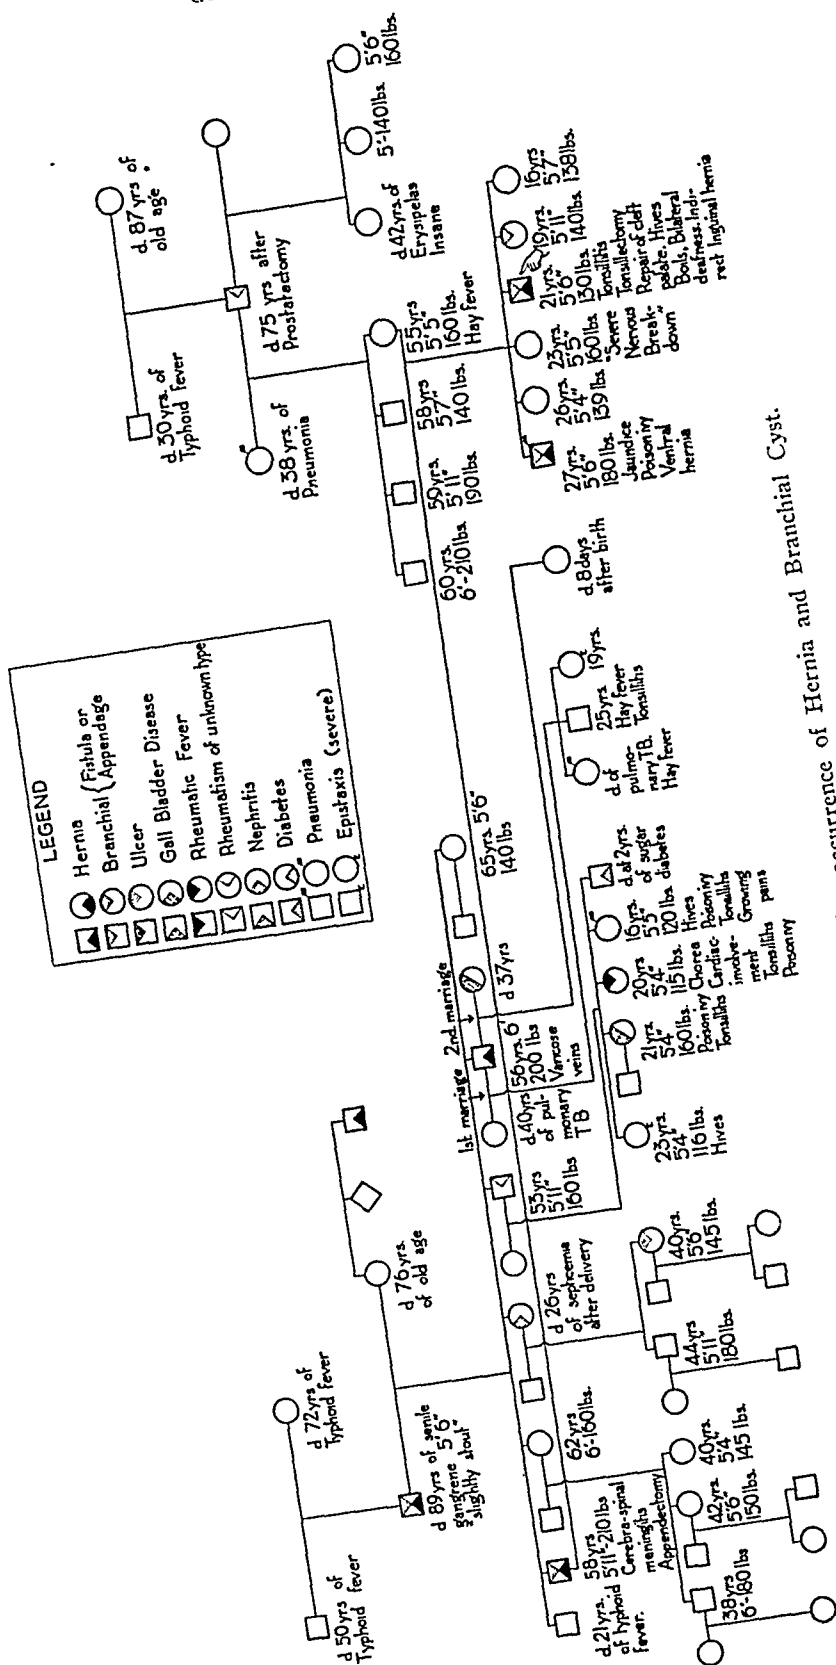

Fig. 4. Family Tree showing occurrence of Hernia and Branchial Cyst.

example of the inguinal hernia with branchial cyst is of interest (Fig 4) Besides anatomical abnormalities, many disturbances in tissue function, either motile or secretory (chemical) are likewise known to be inherited. Some of the most important of these have been discussed by Garrod,⁸ and by Bauer and Ashner.⁹ Recently, White and Pinkus¹⁰ have shown that diabetes (pancreatic tissue secretory fault) is inherited in Mendelian recessive fashion. Some families display one or more of these disturbances in such striking fashion that the underlying genetic mechanism can be accurately inferred. Consequently, the physician who would pluck from his patient's family tree facts which may illuminate the man's total personality, should know at least the main principles of heredity.

While it is not possible within the scope of this article to present a full discussion of all the findings of experimental genetics, there are two principle

Fig 5 Diagram after Morgan showing simple Mendelian inheritance

Illustration by courtesy of Lippincott Co from *The Physical Basis of Heredity* by Morgan

mechanisms which may be mentioned with advantage. The most widely known genetic phenomenon is the one generally called typical Mendelian inheritance. The simplest expression of this arrangement is displayed when two varieties of pea plants, one tall and the other short are crossed (Fig 5). The quality of tallness is stronger than (or dominant to) shortness, so that all the offspring from this first cross are tall. The quality for shortness, however, is not lost, it has gone, as it were, into hiding. If now two members of such a mixed generation be crossed the recessive quality of shortness reappears, and always in the same proportion of one short to three tall plants.

These distinguishing characters which appear in the full-grown plant are dependent upon certain factors which are held in the chromosomal material and then, passed on in fixed proportion to the offspring, are carried out by the factors themselves (Weissmann's determinants, Johannsen's genes), within the cell bodies of egg and sperm during fertilization. The elaborate maneuvers which the gene bearing chromosomes execute can be seen under the microscope. Thus, for example, in many species it appears that the chromosomes differ in shape and size, and that there are always two of each variety. In the preparation for impregnation, the chromo-

1250

somes of both egg and sperm divide into two equal groups, each group containing one member of each homologous pair of chromosomes. One of these groups is cast off in the egg cell or sperm cell. When these two cells unite, each bringing the reduced complement of half its chromosomes, the original number appropriate to the species is reassembled. (Fig. 6) The chance combinations of paternal and maternal chromosomes which can result from the reassemblage is best shown in Fig. 7. Sometimes, individual members of chromosome pairs may break up in the rearrangement and exchange parts. This results in the phenomenon known as "crossing over," (see Morgan) and accounts for the limitless possible combinations of characters in the offspring of a given stock. But the genes, the actual factor bearers, within most of the chromosomes are too small to visualize definitely. Their nature and arrangement have been inferred however, from many thousands of ingeniously devised breeding experiments. Recently it has been shown that in the huge chromosomes of dipteran salivary gland cells, the genes can be seen as transverse beaded bands. Bridges¹⁰ has made maps of these. The present notion is that the genes exist in pairs strung in long strands like a double string of pearls, the members of each pair carrying like factors.

It would appear further that the genes have a variable relation to factors; thus, a gene may carry only one factor or several which determine certain characters in the finished organism; or several factors which go to form a single part may

Fig. 8. Diagram of a portion (five pairs) of the chains of genes in two parents, P and M, and in one of their offspring F, to illustrate the workings of heredity. The father (P) has two defective genes (white) in one of his pairs (the second) and is therefore personally defective. The mother (M) has both genes normal in this second pair. The child (F) receives one from the mother (m) and one from the father (p), so is not personally defective.

Diagram of the results in heredity in cases where one parent (P) has two defective genes (white) in a certain pair, the other parent (M) one defective gene in that pair. Some of the children (F) receive two defective genes in that pair (a) and are therefore personally defective; others receive only one (b), so that such are not personally defective.

Illustration by courtesy of Norton & Co from *The Biological Basis of Human Nature* by Jennings.

be distributed over more than one gene. When there is a fault in the gene structure, it may involve one or both members of the pair. If both members are faulty, then the fault surely goes over into the fertilized cell. If only one member of the gene pair is faulty and the other sound, then either fault or soundness is transmitted. If the fault is recessive (as faults usually are) and is transmitted, it may be concealed because it unites with a sound (or dominant) member from the identical pair of the other cell in the union. The diagrams from Jennings illustrate the principle (Figs 8, 9, 10).

The second fundamental genetic phenomenon to which reference will be made

Fig 9 Diagram of genes to illustrate the results in heredity when each parent has one defective (white) in the same pair. The parents P and M, having a normal gene in each pair, are not defective. Of the children (F), some receive a defective gene from each parent as at a, such will be personally defective. Others receive but one defective gene (b and c), or none (d), these will not be defective.

Diagram of genes in parents and offsprings to show how inferior parents may produce superior offspring. The father (P) has both genes defective (white) in the second pair shown, the mother (M) both defective in the fourth pair, both are therefore personally defective. The offspring (F) receiving one set of genes (p and m) from each parent has no pair in which both genes are defective (white) it is therefore not personally defective. Each parent supplies a normal gene for the pair that is defective in the other parent.

Illustration by courtesy of Norton & Co from *The Biological Basis of Human Nature* by Jennings

here is that which explains the inheritance of sex. The description of this mechanism by Babcock and Clausen is so brief and clear that it is quoted in full.

In certain forms particularly in animal species there is a constant difference in the chromosome complex of the two sexes which provides a splendid illustration of a somatic difference related to a cytological one. The chromosome differences in sex in *Drosophila melanogaster* are illustrated in

Fig 10 Diagram of genes to illustrate the results in heredity when two defective parents (P and M) have both genes defective (white) in the same pair. The offspring (F) then receive one defective gene in that pair from each parent such offspring are therefore personally defective like the parents.

Diagram illustrating how parents showing many heredity defects may produce offspring with none. The father (P) has many pairs of genes with both numbers defective (white) and the same is true of the mother (M). But their defects are in different pairs hence the offspring (F) receive in every pair at least one normal gene (black) and is therefore without the parental defects.

Diagram showing how parents (P and M) having no personal defects may produce offspring (F) with many personal defects. Each parent has a single defective gene (white) in several of his pairs and these defective genes are in the same pairs in each parent. In consequence some (not all) of the offspring may receive two defective genes in many pairs as shown at F such will show many personal defects.

Illustration by courtesy of Norton & Co from *The Biological Basis of Human Nature* by Jennings

Fig. 11. Diagram showing the characteristic pairing, size relations, and shapes of the chromosomes of *Drosophila melanogaster*. In the male an X and a Y chromosome correspond to the X-pair of the female. On the basis of X equals 100, the length of each long autosome is 159, of each small autosome 12, of the whole Y 112, of the long arm of the Y 71, and of the short arm of the Y 41. (From Bridges.)

Fig. 12. Diagram to show chromosome relations in the inheritance of sex in *Drosophila melanogaster*. The sex-chromosomes are represented in full black in order to focus attention on them.

Illustration by courtesy of McGraw-Hill Pub. Co. from *Genetics in Relation to Agriculture* by Babcock and Clausen.

Fig. 11. In the female there are four pairs of chromosomes, each of which consists of two exactly equivalent members, one of which is like the two members of the corresponding pair in the female, but the other is morphologically different; it is longer than its mate and is J-shaped instead of straight. The members of the three pairs of chromosomes which are alike in the two sexes are called autosomes; those of the unlike pair are called sex chromosomes. The sex chromosomes of the female and the similar one in the male are called X-chromosomes, and the unlike member in the male is called the Y-chromosome.

The way in which the chromosome difference in the two sexes is preserved from generation to generation is shown diagrammatically in Fig. 12. Beginning with the parents, the diploid number is shown in the circles. In the female, the three pairs of autosomes are outlined and the X-chromosomes are drawn in full black to focus attention upon them. Correspondingly, in the male only the X- and Y-chromosomes are drawn in black. The reduction divisions in the female result in the production of eggs each of which contains two large curved and a small autosome and one X-chromosome. In the male, the reduction divisions give rise to two kinds of sperm in equal numbers; one containing three autosomes and an X-chromosome; the other, three autosomes and a Y-chromosome. In the ensuing fertilization, the union of an egg

Fig. 13. Sex-linked inheritance of white and of red eyes in *Drosophila*. Parents, white-eyed male and red-eyed female; F_1 , red-eyed males and females; F_2 , red-eyed females and equal numbers of red-eyed and white-eyed males. A black X indicates an X-chromosome bearing the gene for red eye, a white X bears red eye. O indicates that an X is wanting; Morgan replaces it by Y. (From Conklin, after Morgan.)

Illustration by courtesy of Cambridge Press from *Genetics and Eugenics* by W. A. Castle.

with a sperm containing three autosomes and an X-chromosome produces a female zygote; and the union of an egg cell with a sperm cell containing three autosomes and a Y-chromosome, a male zygote. Obviously, the operation of this mechanism preserves the chromosome inequality of the two sexes, and at the same time accounts for their observed numerical equality.

The X-chromosome, however, does not carry the factor for the sex character alone. Other genes representing factors for other characters are also present. But these go along with the factor for sex

parallelism between certain hereditary family characters which may be seen in clinic, and certain kinds of genetic mechanisms which have been demonstrated in the laboratory.

The first instance from our own series is the case of a woman of sixty-three who came to the hospital with sugar in the urine. In addition, she presented double ptosis of the eyelids, subcutaneous fibromata, a curious redundancy of the visceral conjunctiva, and later died of coronary disease.

Fig. 14 Photograph showing subcutaneous fibromata, double ptosis of eyelids and redundancy of conjunctiva at corneal margin.

and so come to character expression in the new individual precisely as sex does. Characters which are transmitted in this way are said to be "sex-linked." The phenomenon is well shown for the character of eye color in the fruit fly in Fig. 13. As was indicated at the outset of these remarks upon genetic mechanism, further discussion of the subject cannot be entered into at this time. Those readers who are interested are referred for the complete material to the writings of Morgan,¹¹ Jennings,¹² Castle,¹³ and Babcock and Clausen.¹⁴

With the foregoing notions in mind, we can proceed more easily to discuss the

Fig. 14 shows the visible insignia which were so intensively distributed through three generations. In the F. 2, eight out of nine living members of the fraternity show some parts or all of the marks. In F. 3, fourteen out of twenty-two are variously affected. The genetic chart (Fig. 15) which presents all the available facts, seems to show that the defect is inherited from the mother's side of the house. But this point will be further discussed later.

Although Jennings believes that defective characters are in the main recessive, he cites several which are dominant; among these are the conditions of brachy-

Inheritance of Redundant Conjunctiva, Ptosis, and Cutaneous Fibromata

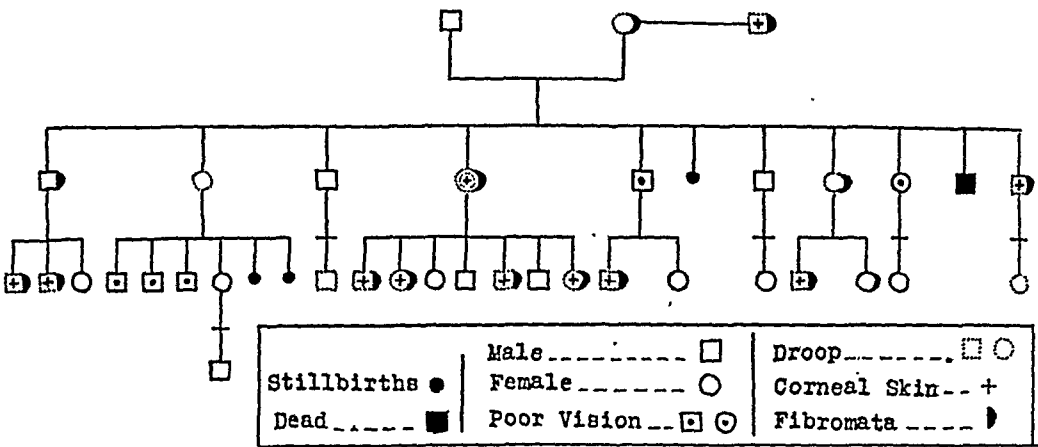

Fig. 15. Diagram of family tree of patient shown in Fig. 14 showing distribution of lesions.

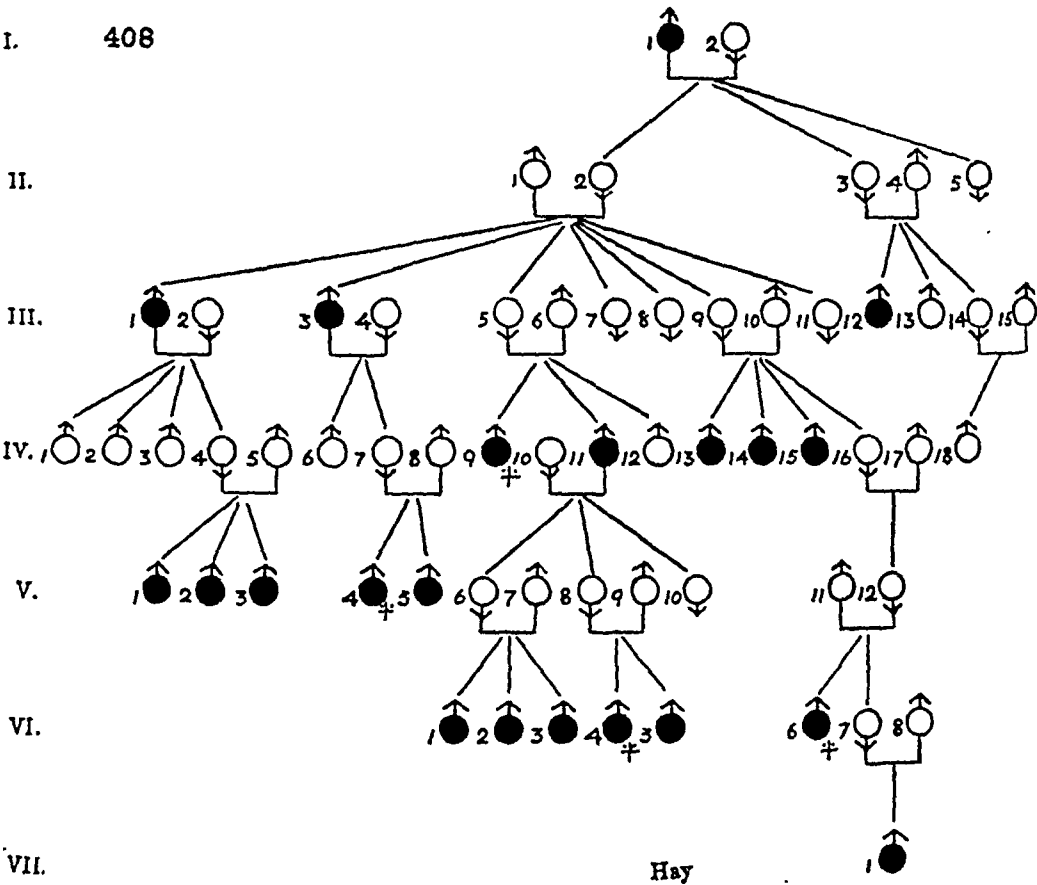

Fig. 16. Diagram showing inheritance of hemophilia. After Bullock and Fildes.

dactylism, and of lateral union of two fingers. It should be remembered, however, that in clinical medicine the question of recessiveness and dominance is further complicated by the fact that a dominant character for susceptibility does not in itself produce the given disease. In the absence of the appropriate external agent, obviously the disease cannot occur. Consequently, in such a situation a dominant susceptibility character may remain undisclosed and so behave as a recessive normally does in the skipped phenotype.

The case under discussion is probably of like nature to those mentioned by Jennings, namely, a dominant defective characteristic, and is especially significant in view of White and Pinkus' recent work on diabetes. The question at once arises whether this patient had diabetes in the accepted sense of that term. The thought presents itself that the islands of Langerhans were functioning inadequately due to mechanical constriction by the overgrowth of interstitial tissue, rather than because of an inherited fault in the germ plasma of the island cells. The defect seems to involve mesodermal tissue in each lesion, and may be explained in one of two ways. Either the fault involved the original mesodermal layer as a whole, or the disturbance is present in the neighboring gene pairs which control the affected parts. This notion has been advanced by Ashner to explain those rare instances in which the same combinations of widely diverse structural defects appear repeatedly in individuals through several generations. In her discussion of this remarkable occurrence, Ashner presents some families in which congenital absence of the patella is found in conjunction with failure of the thumb nail to develop.

The intensity and extent of the defect in the case are so great that one inclines to believe that the patient's father also may have carried similar faulty genes. He was reported to be blemish-free, as were also a few of the descendants. Some of these, however, were still in Europe and not available for examination. This situation presents one reason why clinical genetic studies cannot proceed rapidly. Scattering of the clan, as well as poor memory, too often leave gaps in the evidence. In this instance, therefore, if we

assume that the patient's father likewise carried similar defective genes, either one of the diagrams of gene distribution may be applied (See Figs 8 and 10).

The next example is drawn from Bulloch and Fildes' study of hemophilia (Fig 16). This remarkable disease is especially important for our purpose. In the first place, it illustrates one of the earliest recorded instances of successful preventive medicine through the application of knowledge of the perceptive or intuitive sort. Maimonides (1135-1204) is said to have advised that a boy was not to be circumcised if his two brothers by the same mother, but by different fathers, had died after the operation. There is also reference in the *Tractat Jebemoth* (2d century A. D.) to the rule that a boy must not be circumcised if two sons of his maternal aunt have died from the procedure. The fixed nature of this type of passage of an inherited character through an unaffected mother to half her sons has been shown by laboratory experiments to be due to a defect in an X chromosome of the father. Considered from the standpoint of dominance and recessiveness, it is obvious that sex-linked characters are dominant in the male and recessive in the female. Consequently, the faulty character is one of the so called sex linked ones previously mentioned (See Fig 13). Doubtless a biological principle here finds expression. But one should heed Morgan's warning that as yet it is unsafe to infer from the fruit fly's evidence that there is an identical sex determining mechanism in man.

The foregoing discussion of genetic mechanism and of the hereditary characters stamped upon individual clans was undertaken primarily in the effort to focus attention upon the nature of the individual within the patient. From this standpoint, the family genetic history serves a double purpose. Not only does it help to illuminate the personal identity of the patient, but also it may often aid in the diagnosis of disease by directing attention to a genetic fault in the family which has frequently found expression in a well recognized malady. It is entirely on account of this secondary bearing upon disease probability that Siemens has developed the subject of human genetics so actively in his clinic.⁴ Because of this attitude,

however, which displays perhaps less concern with the concept of constitution in the sense of clinical organismalism, Siemans warns against the danger of assuming that an unexplained malady is due to an inherited (idioplasmatic) tissue fault. He is wary of the geneological chart as not carrying adequate proof of such a fault. He insists that convincing evidence of inherited disease potential is only to be found in the statistical method, and in support of this contention he quotes Fr. Mueller's well-known dictum that "in the whole of medicine a correct numerical count is more valuable than all the brilliant hypotheses." At this point, however, Siemans adds the following somewhat equivocal foot note: "The separation of genetic research into statistical and geneological departments is unjustified. The geneological can only serve for the classification of material; the final appreciation and compilation is always statistical."

There is no doubt that when statistical methods are applicable they carry the kind of conviction which satisfies the mind within the sphere of rational or abstract knowledge to which reference has been made. But then the question arises whether any material in the field of human genetics can ever be sufficiently extensive and precise as to justify its analysis with so refined an instrument as mathematics.* Should this turn out to be the case, we are then forced to accept and evaluate the observable phenomena of human heredity in terms of the sphere of perceptive knowledge or throw them out of court entirely. Clearly, such a course would deny all the experience recorded in folk lore and the literature of medicine.

Now, if we admit that often the genetic fact details supplied by patients and their families are inaccurate and incomplete, it may still be possible to capture the implication of certain trends which are clinically helpful though lacking the final

satisfaction of proof. As a matter of fact, there are many published reports of statistical studies in human genetics, notably those of Hanhard, Siemans, Bauer and Ashner, and latterly Pinkus and White. These last named authors show on a large material that diabetes is an inherited character which follows the course of a typical Mendelian recessive.

In our genetic studies which were undertaken primarily as part of the investigation of the given individual's constitution or personal identity, the material from two groups of patients was likewise considered statistically.

One group of thirty patients suffering from inguinal hernia, provided reliable information on 253 men representing the male constituents of the total population of thirty families. Of them, sixty-one or 24.11 per cent have had hernia. It is interesting to cite here that a hernia rate of 5.1 per cent was reported in about 16,000 health examinations by the Life Extension Institute made on white males.¹⁷ Besides this, 2.1 per cent cases of postoperative hernia were found in the same series. Thus, a total of 7.2 per cent would seem to represent the average hernia rate for the general male population. Further, analyzing the data from the thirty families, it appears that when the patients are excluded, there remains a male population of 233 persons. Of these, thirty-one or 13.9 per cent had hernia. Of the thirty fathers of the patients, fourteen or 46.66 per cent had hernia. Of the fifty-five brothers of the patients, eight or 16.36 per cent have hernia.

In the sixteen families where the father of the patient did not have hernia, there are twenty-two male children exclusive of the patients. Of these, one or 4.54 per cent has hernia. On the other hand, in the fourteen families where hernia is present in the father, there are thirty-three sons exclusive of the patients. Of these, seven or 21.2 per cent have hernia. In view of the small numbers involved in this study, it is obviously unjustifiable to draw general conclusions concerning a possible heredity factor in hernia. Furthermore, the literature is barren of specific data bearing on this point. However, when the findings of this series are compared with those of the Life Extension

*The paper of Pinkus and White is an admirable illustration of the skillful and wise use of the statistical method in human genetics for clinical purposes. These authors are fully aware of the unreliability of information about individuals who have not been personally investigated by the observer. Yet they present very satisfactory evidence of the manner of inheritance of diabetes.

Institute figures, they would seem to present enough implication of an hereditary factor to warrant further investigation.

Our second group study was made on a series of peptic ulcer and of gallbladder families.¹⁸ When these two groups of families are placed side by side, the differences stand out quite as clearly as do the differences in the individual patients of the two groups.

Sex Distribution. The ulcer families are represented by twenty-six male patients and six female patients, and the gallbladder families by five male patients and twenty-seven female patients. No sex selection was made in taking the histories, so long as the patient was able to give intelligent cooperation. In the members of the ulcer patient's immediate fraternity, exclusive of the patient, a sex distribution in the ratio of 138 males to 100 females is found, while the gallbladder families present quite the opposite picture of 100 males to 130 females. There is, then, a tendency for the ulcer families to produce a preponderance of males and gallbladder families a preponderance of females.

Morphology. In general terms a description of the habitus of members of the family was elicited. The terms slender, medium, stocky, and stout were employed. The ulcer families reported seventy-five per cent of the brothers and sisters of the patient as slender or medium build, while the gallbladder families reported fifty-four per cent of the immediate members of the patient's fraternity as stocky or stout. Seventy per cent of the fathers of patients with ulcers were described as medium or slender build, and only thirty per cent as stocky or stout. Of the fathers of patients with gallbladder disease, fifty-five per cent were described as slender or medium and forty-five per cent as stocky or stout. The mothers of patients with ulcers were reported as fifty-five per cent thin and forty-five per cent stout, while just the opposite picture was found among the mothers of patients with gallbladder disease, with fifty-five per cent stocky and forty-five per cent thin. The findings show that the slender and the medium build are in the majority in the ulcer families and the stocky or stout in the majority in the gallbladder families.

Disease Incidence. Peptic ulcer was found in six of the ulcer families, indefinite stomach trouble in thirteen additional families and cancer of the gastrointestinal tract in a further family, a total of twenty, or sixty-two per cent, with a heredofamilial weakness of the gastrointestinal tract. Ruhmann¹⁹ found forty-eight per cent of fifty families with a similar hereditary history; Aschner²⁰ found 65.3 per cent and Spiegle²¹ found sixty-one per cent. Aschner reported that fifteen per cent of the families of healthy persons gave such a history; Spiegle reported 15.5 per cent. Assuming that there is a hereditary influence, the tendency is in the form of a pathologic inferiority of the gastrointestinal tract.

Ruhmann pointed out that definite ulcer is more frequent among the sibs and descendants of the patient, and indefinite stomach trouble is more common among the ascendants. The question arises as to the possibility that this fact may be due to more refined diagnosis nowadays and the closer familiarity of the patient with his own and the succeeding generation. Aschner concluded from her studies of 120 ulcer families that the gene for stomach inferiority is a recessive, but is not sex-linked. She found that in cases in which both parents were affected, fifty per cent of the offspring were also affected. If one parent is sick and the other has a sick heredity, twenty-five per cent of the offspring are affected. If both parents are well but show a sick heredity, ten per cent of the offspring are affected. The smaller number of families comprising our series hardly permits of such an analysis. After working over a long period with patients with ulcer, we have found it hard to conceive that a specific gene weakness is responsible for so complicated a disturbance of the vegetative nervous system as that which results in lesions of the gastrointestinal tract. Nor can we accept the condition as a recessive Mendelian phenomenon in view of the variability of the external influences that may determine its expression.

Among the immediate members of the patient's fraternity, our studies show that 3.5 males to 1 female express gastrointestinal weakness, exclusive of the patient. The mothers show the condition

twice as often as do the fathers. Seven families gave a history of such weakness among the maternal collaterals and only one among the paternal collaterals. In this connection, it should be stated that the maternal line is frequently better known to the patient than the paternal line. In all except one case, the relatives with gastric symptoms were described as of slender or medium built. The gallbladder families show that in the members of the patient's fraternity, exclusive of the patient, indefinite digestive disturbances are three times more frequent in females than males. The condition occurs with about equal frequency in the paternal and maternal lines.

Tuberculosis was found in twelve ulcer families, or thirty-seven per cent. Ruhmann reported a thirty per cent incidence in his fifty families. The condition occurred twice as frequently in males as in females. Pneumonia was reported in fifty per cent of the ulcer families, and again this condition was found to be twice as frequent in males as in females. When it is recalled that the ulcer families are represented by twenty-six males and six females, the preponderance of male susceptibility to diseases within the zone of the pneumogastric nerve in these families is interesting.

Asthma occurred in eight, or twenty-five per cent of both the ulcer and the gallbladder families. Diabetes occurred in only two ulcer families, as compared to seven gallbladder families. Gallstones were reported in two ulcer families; a mother was the subject in each case. This gives a gallstone incidence of six per cent as compared to eight per cent found by Ruhmann. The gallbladder families reported eleven cases, or thirty-four per cent of gallstone. No cases of goiter were reported among the ulcer families, while the gallbladder families reported four cases. Arthritis was found in one ulcer family and 3 gallbladder families.

Psychologic Make-Up. The study of the psychologic make-up of the families offers many difficulties. To extract from the patient a picture of the colorless personality of a brother, for example, is often an almost impossible task. Yet something may be gained from direct questioning about his schooling, occupation, stability in work, marriage, hobbies,

interests and his reaction to any specific situation with which he would be likely to come in contact. To present this phase of the study statistically is obviously impossible. However, a perusal of several selected histories will doubtless go far to show how strongly personality patterns are imprinted in the family.

Summary. The genetic studies may be summarized as follows: 1. There is a tendency for the ulcer families to produce a preponderance of males and the gallbladder families of females. 2. Patients with ulcers are of families in which the long, thin type predominates as contrasted to the gallbladder families in which the short, thick type is in the majority. 3. There is definite evidence in the ulcer families of a heredofamilial weakness of the gastrointestinal tract, sixty-two per cent of the families reporting such a history. 4. Gastrointestinal weakness is three and one-half times more frequent among males than among females in these families, and almost without exception it is found in thin people. Males of these families are also much less resistant to other diseases in the zone of the pneumogastric nerve (tuberculosis and pneumonia) than are females. 5. Diseases of a catabolic nature occur more frequently in ulcer families, and anabolic disease more frequently in gallbladder families.

A third group is formed of material from the families of forty-four unrelated patients suffering from acute rheumatic fever. Only the patients with a history of joint symptoms were accepted. All are of northern European or English extraction. All of these family histories cover two generations, a large number three, and several as many as five. There is a total population of 1,343 persons of whom rather complete disease histories have been obtained.

Of this population there are 205, or 15.2 per cent, individuals, including both our patients and their affected relatives who have a history of rheumatism. Heart cases have not been included in this group unless there was a definite diagnosis of a valvular lesion. Neither have chorea patients been used except when there were also rheumatic manifestations. Now, if the forty-four patients are excluded from the above figures, there re-

main 161 or 12.4 per cent rheumatic individuals in a population of 1,299 persons. As a basis of comparison for these figures, the group of family studies of stomach ulcer and gallbladder patients were employed. In the course of taking these latter histories, all rheumatic manifestations were carefully sought and recorded. In this group, there was a population of 910 individuals whose definite disease histories were known. Of these, forty-five or only five per cent showed a rheumatic history. It would seem fair to assume that this figure represents the incidence of rheumatism in the general population.

Now then, if the immediate fraternities of the rheumatic fever patients are analyzed, it appears that there are 211 individuals in a group formed of the patients and their siblings. Of these 211 people, seventy-three or 34.6 per cent have suffered from rheumatism. In a study of fifty families of acute rheumatic fever made by the Constitution Clinic in 1923,¹⁷ 37.6 per cent of 243 patients and their siblings were found to be affected. A similar analysis of one hundred families studied by William St. Lawrence²² and to which he has very kindly given us access, shows 31.5 per cent affected fraternity members. Now, if the patients are excluded from the above figures and only their siblings considered, it appears in the present study that eighteen per cent are affected, in the second study referred to above, twenty per cent, and in St. Lawrence's 14.7 per cent. These figures approach the 12.4 per cent incidence in the population of the rheumatic families and are considerably higher than five per cent incidence for the general population. The close approximation of the findings in the three separate studies is remarkable. It should be stated that in the present study, nine of Doctor St. Lawrence's families have been reinvestigated and used.

In the present group of patients and fraternity members, there are 122 males and 89 females or a ratio of 137 to 100. The actual cases, however, occurred in 41 of the 122 males (33.5%) and in 32 of the 89 females (35.8%). Thus there appears to be a slightly higher incidence of affected females. Twenty-four of our families are represented by a male patient

and twenty by a female. This selection was purely accidental. If the number of patients is deducted from the total, the ratio of male to female fraternity members still remains high.

In seventeen of the families, rheumatism was found in the paternal line. In these families, twelve fathers give a personal rheumatic history. In the remaining five families, the disease appeared in the father's forebears and collaterals. In twenty-nine families, rheumatism appeared in the maternal line. In these families, seventeen mothers gave a history of rheumatism. In the remaining twelve families, the disease was present in the mother's forebears and collaterals. Hence, not infrequently an unaffected parent whose forebears or collaterals had rheumatism produces a rheumatic child. This suggests the possibility that a parent may carry the susceptibility for rheumatism though he or she may not develop it.

As the analysis of the rheumatic fever family histories proceeded, an unexpected finding was encountered which brings up for consideration the question of specific age susceptibility in children of the same fraternity. In twenty-two families where there was more than one case of rheumatism, exact information was obtained as to the age when clinical symptoms of

rheumatism were first exhibited. Fig. 17 shows the striking correlation between age of onset in members of the same fraternity.

In only two of these families (2 and 14) have two children been affected simultaneously. In Family 2, it was during the patient's second attack that his youngest brother developed acute rheumatic fever. But it is noteworthy that this child was exactly five years old, the same age to a month, as was the patient at his first attack. The third brother to be affected had his attack during his sixth year. In Family 14, there appear both circumstances of simultaneous affection and also age similarity. The patient, a male, was taken sick first at the age of fourteen, his sister next in line in the fraternity at the age of twelve, a year earlier. The third child in line, a boy, was affected at the age of seven, three years earlier, and the fifth in line, a girl, also at seven, but in the same year as the patient. It is interesting to note that in Families 20, 21, and 22, where the first attack in the patient occurred in adulthood, the same age similarity appears in the affected siblings. This does not hold true for Family 19.

Thus, it would seem that the specific resistance against acute rheumatic fever tends to break down in members of a given fraternity at a definite age for that fraternity. It is difficult to interpret this phenomenon in any other way than as the expression of an inherited special "age-resistance" character.

The nature of this phenomenon is not yet clear, but it would seem to be similar to many other biochemical changes which occur in the organism at various ages. It is common knowledge, for example,

Fig. 18. Cross between a Great St. Bernard dog and a dachshund. After Lang (1914).

that the tendency to menstruate either early or late, or the time at which the menopause begins is often characteristic of all the women in a given family. Premature graying of the hair, baldness and the event of puberty are all related specifically to some age in the given family. Possibly the same principle underlies the relationship of certain disease-producing infectious agents to different epochs in the life of a human being. While these are roughly grouped as diseases of childhood, like measles, chicken pox, and poliomyelitis, or of middle life, like pneumonia, the age zones are not strictly circumscribed for the human species, but show remarkable variations which continually reappear in one or another family group.

There is another aspect of clinical genetics which still remains to be discussed. It relates to what may be called the appropriateness of the mating. Possibly this is simply another way of saying: "Will a given cross result in successful offspring." An extreme degree of inappropriateness, for example, is to be seen in the well known cross made by A. Heim and reported by Lang²³ between a Dachshund and a Great St. Bernard. The resultant creature (Fig. 18) is unsatisfactory from every point of view. Its long, heavy body and short legs prohibit speed and agility. Furthermore, if the heart and circulatory apparatus or kidneys follow that of the Dachshund, they would obviously be inadequate for the great body size of the St. Bernard and the animal would soon perish. Another instance of inappropriateness is that seen in Stockhard's cross between a Dachshund and a Boston Bull Terrier. Some of the individuals resulting from this cross possessed the long, pointed upper jaw of the Dachshund and the short, square mandible of the terrier. The mechanical inadequacy of this arrangement for mastication was so great as to require special care in feeding the animal. Free and unassisted in nature and in competition with other dogs at the food basin, this type would inevitably die. Such grossly misbuilt animals resulting from inappropriate crosses do not often find analogous expression in man. Human dwarfs and giants rarely mate. Whether this fact be due to a conscious sense of fitness or to the instinctive working out

of the principle of natural selection or to both is an open question. But, whereas it is clear that grossly malformed individuals usually die off, there are infinitely numerous poorly designed creatures who survive. The inadequacies in the constitution or personal identity of these persons may be of a degree which just permits survival. But they in turn are subject to every sort of maladjustment with their environments ranging all the way on one hand from mental defect through insanity to mild neuroses, and on the other from infectious disease and blood dyscrasias to easily breaking bones.

In the extreme examples from dog breeding given above, the species differences are so great that the inappropriateness of the cross is apparent to everyone. Furthermore, the handicap borne by the offspring is easily visible in the gross disproportions of anatomical structure. But there are many other similarly inherited inadequacies which are invisible concealed within a perfectly formed and unblemished exterior. An excellent example of this situation is provided by the parents shown in Fig 19.¹⁴ Another illustration from our records is the ex-

perience of a man and woman who made deliberately what they had every reason to hope would be a well-calculated eugenic mating. The man was highly intelligent, culture and physically sound, the woman unusually strong and very beautiful. The oldest girl child of this union apparently achieved the hoped for result. She was a rarely beautiful and intelligent child. But she died at eleven years of age from malignant endocarditis following a series of childhood infections, rheumatism, and damaged heart valve. Clearly, the child had received genes carrying unseen faults in the immunity mechanism. These faulty factors had been present, undisclosed in the parents. At present, we possess no means of detecting faulty genes which may be held within the chromosomes of individuals whose external appearance and conduct shows no undesirable irregularities. It may be, however, that increasingly sharp observation of a patient's personal identity or constitution will lead to correlations which will illuminate hidden faulty genes harmless to the bearer but menacing to the offspring.

It has been shown in discussing the first or egg stage of the human being

HEREDITARY CRYPTORCHIDISM

From Corbus and O'Connor

Family S

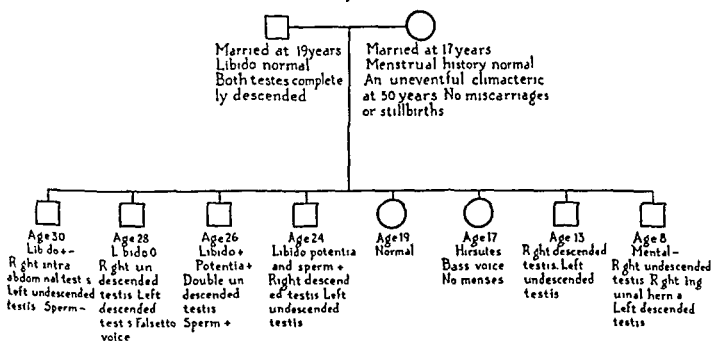

Fig 19 Showing intense distribution of congenital malformation when both parents are apparently normal. Probably an instance where each parent has a single defective gene and these defective genes are in the same pairs in each parent.

that much valuable information about an individual can be gleaned from a careful genetic history. Occasionally, such a study illuminates a basic genetic mechanism which has been demonstrated by directed cross breeding. But in general the far greater service to the patient and his doctor comes from the deeper insight which knowledge of the family history gives to the latter. Not only does information about family characteristics and diseases help in the diagnosis and prognosis of an existing sickness but it pro-

vides some notion of the probability of future ailments. This knowledge may be derived sometimes from the patient's genealogy and sometimes when the information warrants it, from statistical study of groups of families. Beyond these essentially medical values of the family history, however, an historical background is provided which forms a sort of psychological tapestry into which the patient's figure and personal identity is colorfully woven.

NOTICE TO AUTHORS OF PAPERS

Members of the Section on Dermatology and Syphilology of the State Medical Society are requested to submit titles of their proposed papers before January 1, 1936 to either the secretary or chairman of the section.

The scientific session takes place on the mornings of April 28th and 29th, 1936. Louis Tulipan, M.D., 224 East 17th Street, New York City, is Chairman, and Clarence H. Peachey, M.D., 197 South Goodman Street, Rochester, Secretary.

MEDICAL RADIO BROADCASTS

Dr. W. W. Bauer will speak on "Animal Diseases in Man" on December 17, on "Eat, Drink, and be Merry," on December 24, and on "Pneumonia" on December 31 in the

series of broadcasts of the American Medical Association on the National Broadcasting Company's blue network. The addresses are on Tuesdays, at 5 P. M. E.S.T.

TREATMENT OF PNEUMONIA

ARTHUR F. CHACE, M.D., *New York City*

In the past decade there have been over a million deaths from pneumonia in the United States alone. Among infectious diseases lobar pneumonia has ranked second only to tuberculosis, as a cause of death. It is largely an unpreventable disease. Intensive study has developed means by which the suffering of the patient has been ameliorated, and the death rate reduced by symptomatic treatment and by the use of sera. The treatment is more nearly standardized than that of any other infection.

There is a definite relationship between fatigue and resistance to infection. Physical and nervous exhaustion increase the incidence of pneumonia and decrease the ability of the body to withstand the invading organism. About one-half of the patients suffering from pneumonia give a history of having had a "cold" at the time of the onset of the disease. The elimination of all forms of common colds, if ever achieved, will greatly reduce the incidence of pneumonia. It is especially important in this disease, which is as communicable as typhoid, that great precaution should be observed by those coming into contact with it. Bed linen and towels should be carefully handled, masks and gowns worn when possible and extreme care given to the washing of the hands.

The development of immunity against the pneumococcus through the use of vaccines has not proven practical. A temporary, relative immunity, lasting for a few months, has been developed against certain types of pneumonia.

The pneumonia patient should be isolated in a well-ventilated room where the air should be kept fresh, flowing, and at a bracing, moderate temperature. The rigid, open-air treatment has been largely abandoned although moderately cool air is stimulating to the vasomotor system.

The nursing is an all important factor, as is the necessity of sufficient rest and sleep. The taking of the respiration and pulse should coincide with the time for nourishment and treatments, so that the patient may have periods of two or more hours of uninterrupted rest. The diet

should consist of fruit juices, cereal gruels, milk, and broth to which cooked rice or barley has been added. The caloric value of the diet may be increased by adding milk sugar to the fruit juices, while the fermented milks add variety to the diet. If the tongue is dry and furred it is advisable to force liquids in order to avoid dehydration. The coating of the tongue indicates that less protein and more fruit juices should be given. As a rule the patient responds best to a high carbohydrate diet. The use of large amounts of fruit juices also has a laxative effect on the bowels. Where there is evidence of intestinal toxemia, as shown by a coated tongue, bad breath, indicanuria and constipation, it is wise to give a cathartic of either calomel or blue mass, followed by a saline. The bowels should move daily, an enema being used when necessary.

In case of abdominal distention it is well to give from $\frac{1}{2}$ to 1 c.c. of surgical pituitrin hypodermatically, simultaneously with the enema. The pituitrin stimulates the smooth muscle fiber of the heart as well as that of the bowel. The dose may be repeated daily. The application of turpentine stupes is one of the best stimulants for peristalsis. A rectal tube inserted and allowed to remain in situ allows the escape of gas from the lower bowel.

Pleuritic pain is sometimes relieved by immobilizing the chest or by the application of a poultice, although it is frequently necessary to resort to hypodermics of morphine or codeine.

For the control of insomnia and delirium, bromides or one or other of the barbitol family are very useful. The bromide and chloral mixtures control the active deliriums more effectively than the barbitol groups.

The recent work showing the beneficial results in the treatment of infections by artificially produced fever, emphasizes the opinion that a rise in temperature is one of the means that the body uses to combat infection. If this is the case, it is wiser to lower the temperature by artificial means only in those cases definitely suffering

from the pyrexia. In such instances the ice-cap or the alcohol sponge-bath may be used for symptomatic relief.

There is no wholly satisfactory expectorant as most of those in common use upset the digestive tract and have no noticeable effect on the character and amount of the bronchial secretion. Ammonium chloride, in small doses, is perhaps the most effectual. The irritating cough is relieved by giving dilauidide in grains $1/32$, or codeine in grain $1/4$ every four hours, as indicated.

The rate of the heartbeat bears a definite relationship to the prognosis. The more rapid the heart-rate, the less chance there is of recovery. Frequent electrocardiographic tracings, taken before and after the crisis, indicate many changes in the cardiac rhythm. These tracings show that the heart is subject to nearly every type of arrhythmia. The most common ones are: auricular fibrillation, auricular-ventricular block, sinus rhythm and auricular flutter. Digitalis is the best drug for the support of the heart in pneumonia, but it should not be given as a routine for it may then do harm. Its use should be limited to definite indications and the dosage should be prescribed for the specific needs of the individual case. It is most efficacious in auricular fibrillation. Electrocardiographic tracings have been of the greatest aid in evaluating the usefulness of digitalis in pneumonia. The frequency with which arrhythmias increases after the crisis emphasizes the importance of keeping the patient in bed until the myocardium has had an opportunity to recover. Inasmuch as the most frequent cause of death in pneumonia is circulatory failure, either from vasomotor paralysis or from cardiac weakness, it is necessary to supplement the use of digitalis in extreme cases needing emergency stimulation with either adrenalin chloride or caffeine. Strychnine, strophanthus, and camphor have been almost entirely discarded. The use of alcohol is limited to those whose systems have previously been accustomed to it.

Inhalation of oxygen gives the patient more relief than any other agent which we have at our disposal. By its use breathing is eased and the respiratory rate lowered; cyanosis disappears almost entirely, and the pulse improves in quality.

It is probable that in a few cases it actually prolongs life until the patient can build up an immunity against the disease. In a few hospitals, a patient may be placed in a specially built oxygen chamber which is the ideal arrangement. Often only a portable oxygen tent is available, in which the oxygen can be used under the same conditions as in the chamber. However, it is not only practicable but thoroly satisfactory to use a nasal catheter connected by the proper valves and water bottles to a large oxygen tank. The containers of oxygen used for commercial purposes are more satisfactory than the small so-called medicinal tanks. The passage through the water moistens the oxygen and determines its rate of flow. The patient is given forty to sixty per cent of oxygen depending on the amount necessary to relieve his cyanosis. By the old funnel method the oxygen was administered in such small quantities that it was of no benefit to the patient.

Artificial pneumothorax has been used in the treatment of acute lobar pneumonia since 1919. In the last few years it has been the subject of intensive study in various parts of this country. The technic is complicated and the volume of air required is variable. The procedure is not without danger. Introduction of air into the pleural cavity relieves pain and dyspnoea and sometimes causes a temporary drop in temperature. The best results are obtained when cases are treated in the early stages. It has been hoped that the immobilization of the lung would hasten the absorption of serum, lessen anoxemia, stimulate the formation of antibodies, and free the infected occlusion in the involved bronchus. It is still in the experimental stage. Artificial pneumothorax is limited in its usefulness and should be employed only by those most experienced in its use.

When the lung is invaded by the pneumococcus, the defensive systems of the body form immune substances consisting of precipitins, protective bodies, opsonins and agglutinins. These immune bodies are bactericidal and are found in the blood serum of animals inoculated against the pneumococcus as well as in the blood stream of the patient suffering with pneumonia. At the time of the crisis the blood contains the maximum amount of immune bodies. The crisis can be induced

in Type I pneumonia by the administration of Type I anti-pneumococcus serum thereby greatly reducing the mortality in these cases. The benefits in Type II are definite but not as striking as in Type I. The effectiveness of serums in the other types of pneumonia including Type VII, have not been sufficiently demonstrated to warrant their use by the general practitioner. The problem has been to make for Types I and II a refined, potent serum of low protein content to produce a minimum of unfavorable reaction.

About thirty two varieties of lobar pneumonia have been typed. Serums of some efficiency have been developed, particularly for Type VII and Type VIII. It is impracticable to have available for immediate use serums for the rarer types. Up to the present time there is no effective polyvalent serum. The work of Avery, in discovering an enzyme which will dissolve the capsule of the pneumococcus, particularly in Type III, holds out possibilities of future development. The use of these pneumolysins, in destroying the pneumococcus, opens up new vistas in scientific research which may in time revolutionize the present treatment of the disease.

It is imperative that the type of pneumonia be determined as promptly as possible after a diagnosis of lobar pneumonia has been made. A history of serum sickness, allergic phenomena, hay fever or asthma should be a warning for unusual care in the use of sera. The patient should be tested by the placing of a drop of 1/10 c.c. horse serum on the conjunctiva and if the result be doubtful an intradermal injection should be given. If these tests are negative 5 c.c. of concentrated serum may be injected slowly, intravenously. Two hours later 20 c.c. may be given in the same way. If the patient reacts favorably, the dose may be repeated until a total of 100,000 units or more have been given, the amount being determined by the severity of the case. Twenty four hours later, if the patient has improved, about one half the dose should be given. On the other hand, if the patient is worse, the doses should be increased. It is frequently necessary to give serum again on the third day. It is wise to have epinephrine available to be used in case of an unfavorable reaction. This should

be used hypodermatically in a $\frac{1}{2}$ c.c. dose of an 1/1000 solution. The symptoms of the allergic reaction occur immediately and are shock, dyspnoea, sweating, collapse and urticaria. The thermal reaction due to the introduction of foreign proteins into the blood stream, has been greatly reduced since the development of refined sera. The reaction occurs about one hour after the injection of the serum and consists of a chill followed by a rise in temperature which remains high for a few hours and then drops suddenly accompanied by profuse perspiration. The incidence of serum sickness depends largely upon the amount of protein injected. It develops on about the ninth day and is characterized by fever, urticaria and painful, swollen joints. It is treated symptomatically by the use of alkalis, catharsis and soothing lotions, and is usually of only a few days duration.

The most common complication in lobar pneumonia is acute fibrinous pleurisy, which is best treated by immobilization of the chest through strapping, and relief of the associated pain by the use of codeine. Small effusions are usually absorbed but it becomes necessary to withdraw the fluid when there is definite compression of the lung. If the fluid becomes purulent, surgical drainage is imperative. Delayed resolution is particularly apt to occur in elderly patients and necessitates long periods of careful nursing and the use of symptomatic remedies.

Rest in bed is essential until not only the lung has completely resolved but the myocardium has entirely recovered from the infection.

Many factors determine the prognosis in pneumonia. The death rate is about thirty per cent the chance of recovery being greater in the young than in the aged. Certain types of infection are more serious than others. The mortality rate is higher in Type III and lower in Type I. The statistics vary somewhat from year to year. The number of bacteria found in the blood stream is an index of the gravity of the case. The smaller the area of involvement in the lung the greater the chances of recovery.

Summary

The advances in the treatment of lobar pneumonia may be summarized as fol-

lows: more intelligent use of the cardiac stimulants, particularly the indications and dosage of digitalis, made possible by the information obtained by electrocardiographic tracings, the more efficient use of oxygen therapy, and the administration of refined sera in Type I cases and, to a lesser extent, in Type II.

Successful treatment of pneumonia follows the best traditions of the medical profession in that the physician treats the

man who suffers from the disease as well as the disease itself. This requires careful nursing, making the patient as comfortable as possible and installing in him an optimistic spirit.

Although the most dreaded of all diseases has not yet been conquered, each year pneumonia becomes better controlled, the mortality rate is reduced and the realization of its ultimate eradication draws nearer.

525 PARK AVENUE

CUTANEOUS CALCINOSIS

MAURICE J. COSTELLO, M.D., *New York City*

In the past decade more cases of abnormal calcification, especially cutaneous calcinosis, have been reported than in the previous fifty years when it was first described by Weber in 1878. It is generally known that calcification does not occur in normal tissue, except in bone and cartilage and in metastatic calcinosis where there is a depletion of the calcium reserve.¹ Dead, diseased, or degenerated tissue that is not absorbed will undergo mineralization, usually by infiltration with calcium salts. This is a matter of common experience at necropsy when deposits of calcium are seen in various organs, in caseous tuberculous nodules of the lungs, in antecedent fat necrosis involving the aorta and cardiac valves, and in the pleura.

The clinical appearance of cutaneous calcinosis (*calcinosis circumscripta*) which means the abnormal deposition of calcium salts in or under the skin, varies but little in the descriptions given by the several observers. Nodules, plaques, and tumors are seen varying in size from a pin head to a filbert. They are usually of stony hardness and occur most frequently on the palmar aspect and sides of the thumb and first two fingers, on the palms, the extensor aspect of the elbows and knees, and at the wrist and ankle joints. They are almost invariably situated over or along the course of the flexor tendons of the hands, and the extensor tendons of the elbows and knees. They are seen in locations subject to frequent trauma and repeated muscular activity.

At the onset, the skin over the nodules is normal in appearance, and as the lesions enlarge they become painful. The inflamed skin adheres to the lesions, which later break through and sluggishly discharge a white creamy material with small gritty particles of calcium. After a considerable time the tumors decrease in size. They will disappear if all the calcium is evacuated but usually recur to repeat the process.

Pathologic calcification, evidenced by the precipitation of calcium salts in secretions and excretions, is understood. I refer to urinary and biliary calculi. Much less is known about the deposition of calcium salts in the tissues and especially in the skin, as in cutaneous calcinosis.

Cutaneous calcinosis may be local or general. In the local form calcification is seen in tumors such as epithelioma, sebaceous cysts, etc. In the general or metastatic form increased amounts of calcium are found in the blood resulting from constitutional diseases, such as osteomyelitis with extensive bone destruction, caries, and lymphatic leukemia. In metabolic calcinosis there is no bone destruction.

Chemical examination of the nodules, according to Maloney and Bloom,² showed the presence of a large amount of calcium phosphate and a small amount of calcium carbonate. The computed ratio of the different examinations by the various observers was approximately 7-1. Several writers have reported a predom-

nance of calcium carbonate

Weidman and Shaffer³ in a careful and painstaking study reported the presence of intracellular and extracellular infiltration of calcium in the epidermis. The collagen bundles of the corium were similarly altered, as were the lumina of the blood vessels, the endothelial cells of the capillaries, veins and arterioles. All the layers and structures of the skin were involved except the sebaceous glands. Calcium was found in the sweat glands and ducts, Pacinian corpuscles, nerve trunks, and corium. The important point was that the calcification was intimately associated with infiltration of fat. Their interpretation was one of an antecedent fatty alteration followed by eventual calcification.

Nearly all the cases of metabolic calcinosis except this report show a normal blood calcium. Those of the metastatic group resulting from bone resorption show a high amount of blood calcium.

The age of the patients ranged from

two weeks to sixty-five years, the infants less than one month probably presented a condition of subcutaneous fat necrosis of the new born. In adult cases women seem to be more often affected than men.

Other diseases have been associated with cutaneous calcinosis—tuberculosis of the lungs, rheumatism and rheumatoid arthritis, osteomyelitis, caries, chronic nephritis, and lymphatic leukemia. Scleroderma and sclerodermatous changes are frequent accompanying clinical manifestations, as are Raynaud's disease and arteriosclerosis.

Thomas, in discussing the case of Weidman and Shaffer, reported that a fourteen year old boy with metastatic calcinosis at autopsy had markedly enlarged parathy-

roids. Hubbard and Wentworth's⁴ patient also had hyperplasia of the parathyroids.

Metastatic calcinosis, when accompanied by constitutional disease such as osteomyelitis, lymphatic leukemia, and parathyroiditis has a poor prognosis, the outlook depending on the associated condition. In the metabolic cases the outlook as to life is good.

Case Report

N.D., a white unmarried woman, aged 44, was first seen by Dr. Howard Fox on September 5th, 1929. Since early childhood she had profuse nose bleeds on the average of three times a week. These continued until her late adolescence. Even now she has a nose bleed when fatigued.

Coldness of the hands and feet and generalized chilliness, especially at night have been almost a constant annoyance since childhood.

Typical Raynaud's phenomena have been experienced by the patient since the winter of 1918. She had marked blanching and numbness of several fingers and toes, followed by cyanosis and tingling of the parts affected. She had a radical antrum operation in April, 1924. In 1925 her tonsils were removed and a few teeth were extracted for the relief of headaches. She also had a

herpes zoster of the right side of the neck. She has always had a low blood pressure. Her menstrual life has been essentially normal except in 1922 when she had severe pain and irregularity which was easily corrected in a short time.

When seen in 1929 the patient stated that she had had a skin condition for almost four years. It began as small lumps, the first the size of a pea on the left elbow which appeared gradually, was accompanied by pain, and excised at the end of six months. Three others followed in the same location and were also removed surgically. The pathological examination was said to have shown old tuberculosis. This was probably similar to the histological picture seen by Tipl,⁵ Milian,⁶ and Lewandowsky,⁷ who found foreign body giant cells. She also had one on the tip of the index finger of the right hand and one on the internal malleolus of the left ankle.

Raynaud's phenomena have continued since 1929 and pea to coin sized painful and painless nodules and plaques have developed slowly, the pain depending on the location and stage of development of the nodules. These occur on the tips, palmar aspect, sides of the thumbs and first two fingers and the palms, those parts used most frequently and subjected to repeated trauma.

Generalized arthritic pains with swelling and thickening of the fingers and toes, and an increase in the size of the hands and feet are the patient's greatest complaints. Five years ago she wore a size five glove, she now wears a seven and a half.

The patient works daily and is very active although annoyed by the painful nodules, swelling of the hands and feet, arthritis, and an almost constant feeling of fatigue. She also has a grapefruit sized lipoma on the left buttock, but thinks that this followed an injury in childhood.

Her mother, who died at the age of 71, at necropsy showed marked atheromatous changes in the arterial vessels of the brain and a number of atheromatous plaques on the mitral and tricuspid valves, and the aorta. This loses its significance in a woman of this age. Her father died of angina pectoris; one sister is living and is in poor health; her sister's son, aged 12, also has had frequent profuse nose bleeds.

In the treatment of cutaneous calcinosis, it is first necessary to make the patient as comfortable as possible by incising the skin over the painful nodules under local anesthesia. About a dozen nodules have been treated in this manner. It is best to make an incision and then try to remove the nodule in toto. Not infrequently, before this is possible, a creamy material is dis-

charged and the calcium stone itself becomes fragmented in endeavoring to remove it. I have found it necessary to thoroughly curette the base, the surrounding skin and the sides of the wound to break up the calcium infiltration of the skin. The wound is allowed to drain without suture. It heals slowly, sluggishly discharging small granules of calcium. It is important to remove all the particles of calcium, as, if any are allowed to remain they will act as a "catcher" for the further deposition of calcium salts and the operation will have to be repeated.

Large doses of x-rays, both filtered and unfiltered, had no effect in arresting the progress of a lesion or in curing it.

A half dollar sized calcium plaque on the right knee became definitely softer with a tendency to break down after ten diathermy treatments.

The salicylates were given for the arthritic pains with moderate relief. Disodium phosphate (2 grams, three times a day) as recommended by Craig, Lyall,⁸ and Kennedy,⁹ after a trial of several months had no effect on the lesions.

There is a possible relationship between the arrest in the development of new nodules and the dietary suggestions such as fat, salt, and calcium poor diet.

In the past ten years there have occurred on the face, neck, chest, extremities and the mucous membranes of the lips a number of sparsely distributed, smooth, non-elevated, rectangular and oval patches of telangiectasia. They vary in size from a pin point to that of a twenty-five cent piece. The bony configuration is somewhat asymmetrical and there has been gradual thickening of the features.

Summary and Conclusion

A typical case of the metabolic form of cutaneous calcinosis has been observed, studied, and treated over a period of six years.

This patient has two rare diseases cutaneous calcinosis and multiple hereditary telangiectasis with recurring hemorrhage.

Raynaud's phenomena, painful calcium nodules in the skin, a lipoma, arthritis and a high blood calcium when first observed, followed by a normal blood calcium later and a leucopenia are the high lights of the study.

Trauma, local nutritional disturbance caused by Raynaud's disease, increased

muscular activity and changes in the blood calcium, phosphorus and cholesterol are among the known factors influencing the deposition of calcium in the skin. The exact mechanism is imperfectly under-

stood. This case differs from the others reported in that the blood calcium was high in the beginning and gradually returned to normal.

Discussion

DR. DAVID BLOOM, *New York*—The case reported by Dr. Costello resembles clinically very much the case reported by Dr. Maloney and myself (*Arch. Dermat. & Syph.*, Feb. 1931). The essential differences between the two cases in findings which may be of etiologic importance are: the presence of signs of endocrine disturbance and a history of severe nephritis, the apparent association with Osler's hemorrhagic telangiectasia and an increased calcium content of the blood in the case reported by Dr. Costello. The difference in the last finding between the two cases may be explained by the fact that in our case the affection was of seven years duration, and the calcinosis, as we have described it, was an end result of the disturbance of calcium metabolism which was brought on by the severe nephritis seven years previously.

I feel certain that in the beginning of his illness the calcium content of the blood was high.

I consider the report of this case of great value because of its thoroughness. Calcinosis metabolica is a rare disease and its etiology still obscure. There is disagreement regarding the exact pathogenesis of the formation of the calcium tumors. Any facts observed in association with this affection may some day throw light on the etiology. These cases, when observed early enough, should undergo a thorough examination for calcium metabolism, when put on a diet either rich or poor in calcium. Such cases should also stimulate the physiopathologist in finding adequate methods for the elucidation of the calcium metabolism in the body.

HOW THE "WASHINGTON PLAN" IS GOING

The Washington Plan of medical care has become so well-known nationally that its coordinator, Ross Garrett, has been called upon by the medical and dental societies of St. Louis, Missouri, and Newark, New Jersey, to help them establish similar plans which are now under way. In addition, Mr. Garrett is working by invitation on surveys for the professions of 15 other large cities that desire to use the Washington plan in whole or in part. The main interest very naturally lies in the Medical Dental Service Bureau unit of the Washington plan, and it is, therefore, of interest to note that from an humble beginning of \$1,974.90 in gross revenue for March of this year its business has increased to a point where it touched \$14,673.82 for its maximum month. That the sponsors' fondest hope for a gross revenue of \$120,000.00 for the first full year of operation is to be

very greatly exceeded, is gleaned from the published report of the Bureau's Board of Directors showing \$84,989.95 in gross revenue for the first 7 months. Of this amount, 52 per cent came from all members of the professions and 48 per cent from hospital patients.

A surplus of \$1000 in September was used in part for ethical publicity and business development, and resulted in a large increase in new business. Furthermore, as we read in the *Medical Annals of the District of Columbia*: "The staff at the Bureau is daily receiving letters of commendation from members of the professions and patients whom it has had the opportunity to serve. The hospitals have been unstinted in their praise for the situation the professions have helped to create for them in handling many classifications of their work."

EDITORIALS

Anent Social Service

Social service is the application of a newer science which purports to study all phases of the individual's needs. In making studies of these needs, the accumulated experiences of the past must be comprehended, and where found to be good, affirmed. The development of the civilized state brought with it a larger knowledge of what has been termed "the humanities," and this is playing a larger role as sociological science develops. Medical service is the greatest factor in the practical application of social science, because in the practice of medicine there is found a combination of applied scientific measures, coupled with a knowledge of the effect of both social and of economic factors upon the personality of a sick individual. Wisely to practice medicine is to apply the scientific knowledge to the individual's needs adjusted to his social level and economic resources.

Under these circumstances it seems strange that most of the educational institutions which train and qualify social workers do not utilize to the utmost the particular fitness of the medical trained observer in teaching social science. Because of this lack, it is not surprising that the results of the work of most social research lack the insight which the medical philosopher could contribute.

Revision of the teaching schedules along such lines would strengthen the students taking social service courses and remedy this lack of comprehension of medical fundamentals of service.

Observers, trained medically as well as in other branches of the humanities, would be less inclined to stress schemes for cheaper medical care, but would know that the maintenance of the highest scientific quality in medical care must always be a primary consideration, and that all social schemes must be submitted to this test, which can under no circumstances be involved in compromise. Social workers and research students trained thusly, would put less emphasis on surveys of illness and disease, and more stress on studies to eliminate deleterious factors concerned with food, clothing, housing, and working conditions.

Comprehension of steps to eliminate unsanitary housing, living and working conditions would do more to lessen incidence of disease than almost any other social activity; and it would do much to better the fine record written in mortality and morbidity and preventive medicine by the American medical profession.

We have, upon occasion, criticized the poorly trained social worker. As a profession we have had to combat his make-shifts to social reforms, predicated upon

unsound premises. These men are hardly at fault. The error lies in the training they receive. Can we not confidently expect that the great institutions of education,—that our universities will recognize this lack in fundamental training and remedy it?

In the evolutionary phases which social service, including medicine is undergoing to meet the demands of the new era of cooperative endeavor which is upon us,—there will be place and position for those who study the individual's needs and learn the formula of how best to supply them under our parliamentary system of government.

The Compensation Schedule

In accordance with statutes enacted last spring, the Medical Society of the State of New York has submitted a complete schedule of medical fees to the Department of Labor. The proposed charges cover the entire range of compensation work, establishing a differential fee scale according to time and place and the nature of services rendered.

The moderation of the suggested schedule reflects the sincerity of the profession's desire to see the medical aspects of workmen's compensation established on a high ethical and scientific plane. Organized medicine realizes the financial limitations of a system supported by insurance funds and has made substantial concessions to these limitations.

The progress of compensation would be materially hastened by establishment of the minimum fee scale required by law. Having made generous concessions in the interests of the injured worker and industry, the profession hopes that its proposed schedule will be accepted without drastic change or delay.

Most of the rank abuses in workmen's compensation grew out of the suppression of fair medical competition. The new law provides for the free choice of physicians but unless an adequate scale of minimum fees is fixed, competent practitioners will refuse to participate in industrial work

and the field will be overrun, as before, by the incompetent, the inexperienced and the dishonest.

There is a financial level below which painstaking service cannot be rendered, save at a loss. Any drastic reduction in the scale submitted by the State Society would send compensation fees below that level and invite incompetence and corruption.

The Hospital as the Center of a Social Service

Dean Rappleye of the College of Physicians and Surgeons, Columbia University in his recent report to the President of the University, stated that American hospitals must be adequately financed on a community basis and their function more closely adapted to present day needs. He stressed the fact that the hospital represented a base of operations for all forms of community medical services, that it had a type of medical organization readily to be amplified to cooperate in home nursing and home medical services through its out patient service and other channels. It is the most satisfactory means to preserve high standards of professional performance.

While at this time it is not our intention to elaborate and critically examine all the implications which the plan outlined by Dean Rappleye entails yet using the outline of the hospital as the community's health center for a workable idea, certain fundamentals may be discussed.

In the first place, all recognized, ethical physicians must be attached to the hospital staffs. The necessity of this is obvious. In the second place the hospitals should be supported by government subsidy, and the physicians working in them, serving the indigent of the community should be paid. This should be accepted in principle for both the hospitals maintained by taxes, and also for the voluntary hospitals. The latter carry part of the community's burden, in caring for indigents who cannot be accommodated in tax maintained hospitals.

This is particularly true in New York City. Furthermore, this will alleviate the needs of the younger group of medical men who, just starting upon their medical careers, will, in return for good high grade medical services delivered under the eye and supervision of their seniors on the hospital service, receive a subsidy in the form of pay for services rendered to the wards of the community. Since the adoption of the Booth report we have held that the indigent are a proper charge upon the community funds raised by taxation, and the physician should not be twice taxed, once for his share as a citizen of the community and again as a group,—doctors—taxed in services given gratis, when all other groups concerned with the indigent's case are paid.

Lastly, regulations should govern the subsidy. Taxation can sustain, control, and also destroy. It is a potent weapon. Here it should be used to control practices upon which the organized profession frowns. Hospitals should not engage in active competition for public patronage. They should never be run for a profit. Every rule of conduct enacted for the protection of the public and heretofore obligatory upon individual physicians should be made to apply to the hospital. Advertising, solicitation, self-aggrandizing praise, exorbitant claims of superior service,—and "cut-rate" fees must be obviated. There must be no lowering of the high standards of medical practice, but rather continued efforts to enhance these standards.

With such fundamentals disposed of, the proper study of the plan to make the hospital the health unit of the community may be started. The outline scheme contains none of the un-American implications which have been presented in other schemes.

$$2 \times 1 = ?$$

The Federal Resettlement Administration headed by Rexford G. Tugwell has put the multiplication table to some strange uses. Up to the middle of

November the twelve thousand and more administrative workers in this unit had provided only 5,072 relief jobs. Two times one, in this case, is an understatement of the number of bureaucratic employees required to put a man to work under the national resettlement program.

The higher multiplication tables must be invoked when the question of compensation is studied. In November relief workers engaged by the Resettlement Administration were receiving \$300,000 a month in wages. Multiply this figure by five and you are still a quarter of a million short of the monthly salaries paid the administrative force. In other words, when the intrinsic costs of work are multiplied by bureaucratic expenditures, the result is something to make the taxpayer sit up and take notice.

Mr. Tugwell's aides explain that seasonal difficulties prevent full employment under the Resettlement Administration at this time. Even when the peak is reached, however, it is estimated that there will be one administrative official to every twelve relief workers—a rather high overhead for an employment service!

The situation in the Resettlement Administration is a repetition of European experience with compulsory health insurance. In Germany the Krankenkassen employ almost as many administrative workers as physicians. In England bureaucratic expenses consume a substantial portion of the insurance fund each year. The nation's allotment for health purposes is depleted by the upkeep of a vast bureaucracy which does nothing to improve the level of medical care but interposes a vexatious mass of red tape between doctor and patient.

Compulsory health insurance does nothing that cannot be accomplished by systems like the Geib-Vaughn plan—and the latter does not require a costly administrative bureaucracy. American labor should consider whether it is worthwhile to support a directorial set-up like that in the Resettlement Administration in return for the dubious promise of compulsory health insurance.

The Bactericide of Surgical Maggots

The use of surgical maggots in the treatment of suppurating cavities, particularly those involving the long bones, has yielded gratifying results in a large proportion of instances, but the nature of the curative property possessed by maggots in their action against pyogenic infections has been an undetermined factor. It is of particular interest, therefore, that Simmons¹ has been able to obtain a potent bactericidal principle from surgical maggots, which, *in vitro*, is capable of killing completely all organisms in saline and broth suspensions.

Unlike the ordinary disinfectants now in common use, the material obtained from the maggots exhibited a lesser decrease in potency following the addition of organic material to the broth cultures. The exact mode of action by which this substance destroys bacteria is as yet not clear. That it is not a bacteriophage has been demonstrated by its thermostability and by other reactions. It does not cause the death of organisms by lysis. In itself, it is nonviable and cannot be destroyed by the ordinary process of autoclaving for twenty minutes at ten pounds pressure. Simmons was able to dessicate this material and to demonstrate that in this condition it retained its bactericidal property for a period longer than when preserved in aqueous solution.

To a degree, the presence of this substance would explain the remarkable results of maggot therapy against infections caused by hemolytic streptococci, staphylococcus aureus, and *Clostridium Welchii*. Since the use of live maggots is not always feasible, for one or another reason, the isolation of their germicidal principle and its preservation in dessicated form may eventually afford a means of disinfection more dependable than those now employed. A new field has been

opened for the investigation of living organisms as a potential source of useful and hitherto unknown bactericides which may prove to be of inestimable value in the treatment of bacterial suppuration.

Nonspecific Colitis

There is no more specific manner in which to indicate our ignorance concerning the etiology of a disease than to designate it by a generic term preceded by the word "nonspecific", "idiopathic", or "essential". The term "nonspecific colitis" in itself is strongly reminiscent of Axel Munthe's description of colitis, "Nobody knew when it came, nobody knew when it went away".

Nevertheless, a lesion exists wherein an inflammation of the colon cannot be accounted for by the more specific causes for this pathological change. It has occurred to Hare¹ that this type of colitis may be dependent upon an allergic background. An investigation of thirty-eight cases of nonspecific colitis revealed that approximately eighty-five per cent of them gave a definite history of allergy in either themselves or in members of their family. Asthma, hay fever, urticaria, and migraine were some of the allergic conditions complained of in addition to the intestinal disorder. Hare distinguishes this type of colitis from others in that the mucous membrane presents an abnormally granular appearance and bleeds readily when disturbed. Ulceration is not always present.

The outward manifestations of allergic phenomena are well-known but it is highly probable that others exist which as yet are undiscovered. Mucous membrane is a vulnerable point in allergic individuals. In hyperesthetic rhinitis, hay fever, and asthma, changes in the mucosa are observed in the respective areas where these lesions exist. It seems plausible therefore, that the mucous membrane of the intestinal tract may likewise become

¹ Simmons, S. W.: Bactericidal Principle in Excretions of Surgical Maggots Which Destroys Important Etiologic Agents of Pyogenic Infections, *Baltimore Journal of Bacteriology*, 30:253, Sept. 1935.

¹ Hare, D. C.: Allergic Factors in Etiology of Nonspecific Colitis, *Lancet*, 2:767, Oct. 5, 1935.

altered by an agent to which a person is sensitive. Continued investigation into the history of patients suffering from a colitis of undetermined origin together with extensive tests to determine the presence of sensitization will add further to our knowledge of this subject.

CURRENT COMMENT

"IT IS TO BE REMEMBERED that collective effort in getting medical service is a comparatively new thing. It is out of line with what has hitherto been the long tradition of medical practice, namely, doctor and patient dealing with each other alone in a confidential relation that has proved itself, on the whole, of the most enormous value. * * * Disregard of what has been found to be valuable and essential in medical practice: namely the responsibility of the family doctor for the family, has caused the path of progress to be marked by many monuments of failure when mistaken efforts have come to grief. We need results that are best in the end, not the quickest results."—From the address of Mr. Richard M. Bradley, a Trustee of the Thomas Thompson Fund, before the Windham County Health Council, Brattleboro, Vermont, October 19, 1935.

WILLARD C. RAPPLEYE, Dean of the College of Physicians and Surgeons, in his report to Columbia's President, among other things says, "It has frequently been suggested that the United States should adopt one or another of the plans (of sickness insurance) which have been used abroad. * * * It does not follow that a satisfactory solution for the situation in Germany in 1881, for example, is the program which should be applied in the United States in 1935."—(*New York Herald Tribune*, November 26, 1935.)

MEN HOLDING PUBLIC OFFICE, like private individuals, should be judged by their actions and their statements. It is not well to attribute to any man less worthy motives than those that he professes. * * * Thus does Albert Shaw discuss "Utopia by Purchase," in the December 1935 *Review of Reviews*. Comparing our present spending spree with conditions in Bagdad in the time of Haroun Al-Rashid, he says, quoting from an available epitome of the career of this ruler, "No caliph ever gathered around him so great a number of learned men, poets, jurists, grammarians, cadis and scribes, to say nothing of the wits and musicians who enjoyed his patronage." He further quotes a certain reference book which, though admitting the reality of the golden era that

Haroun inaugurated, would have us think that toward the end of his administration he had a bad time with his vizier and other cabinet officials and bureaucrats, and also with his near relatives; and that "his other unreasonable acts caused general disorder and rebellion in his realm." * * * Shaw concludes this comparative comment with, "But we will risk any standing we have among students of monetary statistics when we venture the remark that Haroun's dinars would not have gone very far if matched against the Roosevelt dollars that Harry Hopkins is handing out. We are glad to have the actors, artists, and musicians considered by our dispensers of bounty. The white-collar people are more helpless when out of work than farm hands and the bricklayers. We do not like to see artists and musicians boondoggling at rough jobs on highways or in sewer trenches for which they are not fitted. * * * The worst thing that can be said about federal relief as a social influence has to do with an evident decline of the spirit of self-help. When a family is drawing enough money from relief * * * he sticks to the government relief list, and loses courage, energy and manhood."

"WITHOUT THE WHOLE-HEARTED cooperation of those members of the medical profession who gave their services free, or for the slight payment our relief authorities were able to provide—payments which were hardly more than tokens of appreciation and partial contributions toward the doctor's expenses—many of our citizens could not have survived the depression." From the address of Governor George H. Earle, at the opening-session of the State Medical Society of Pennsylvania.

THE *Detroit Medical News* carries the story that the Detroit Council had approved the motion "that all welfare patients, after one treatment be referred back to a private practitioner, in both government-supported and community chest-aided dispensaries and welfare departments."

"IT REMAINS THEN a fact that as long as the physicians are giving this great amount of service to the County Hospital (about \$50,000) and saving the county tax payers more than a half a million dollars that they should control the medical situation without the interference of any lay boards or organizations that are constantly seeking changes," says Dr. Clyde P. Dyer, Editor, *St. Louis County Medical Bulletin* for November 22, 1935.

ROBERT H. HAYES, SECRETARY of the Chicago Medical Society, writing in its *Bulletin*, commenting on the action of the

Attorney General of New York in his legal attack on the Life Extension Institute, Inc., remarks that the Attorney General charges the Life Extension Institute, Inc., with diagnosing, prescribing and treating diseases of humans, and with having "continuously and habitually practiced medicine," as defined by the educational laws of New York State. * * * "Success and best wishes to the New York Medical Society and Attorney General Bennett for their attack on the non-medical practice of medicine by chain store methods."—Thank you, Dr. Hayes.

"IN THE COURSE of every week, radio listeners are inveigled into hearing 116 broadcasts concerning the therapeutic merits—not merely properties—of an array of obnoxious and dangerous nostrums. The bait consists of the highest class radio talent available, and in consequence must cost a considerable sum. The total amount spent for this publicity would pay for the proper care of that great group of neglected individuals visualized by the Foundations in their plea for compulsory Health Insurance. Apart from the economic extravagance involved, this condition of affairs constitutes a public health menace which we should all recognize. Many of the "Funds" have investments interlocked with those of the nostrum manufacturers and the reason for their inertia in this regard is obvious. The Philadelphia County Medical Society invites its members to participate in its Radio Program. Every five minutes utilized by them may be considered as at least keeping some nostrum off the air."—*The Weekly Roster and Medical Digest of Philadelphia*. Repub-

lished in the *St. Louis County Medical Bulletin*, November 22, 1935.

AMONG THE COURSES listed for Thanksgiving by the *Bulletin* of the Monroe County Medical Society is the fact that "it appears that socialized medicine is not just around the corner, and is evidencing costivity at early flexures" and "there remains the satisfaction of being a member of a social group whose distinction lies in its unselfishness, its ready recognition of its own shortcomings, and its generally high standard of ethics."

"THE ROSENWALD FUND has just appropriated a quarter of a million dollars to further socialization of medicine," thus says a circular letter from the *Debaters Information Bureau* under date of November 22, 1935.

THE *New York Herald-Tribune* of November 26, 1935, carries an editorial on "Harvard and the Nation." After commenting on the scholarship announcements and the refreshing news that the especially gifted students are to be stimulated, the editorial makes a significant quotation from a statement of President Conant, to wit: "During the years to come it is possible that universities which have a maximum degree of independence from governmental support will fulfill a role of special significance in the maintenance of intellectual freedom." If education is to be on guard to protect its intellectual freedom from governmental control, how much more is it to our purpose to maintain medical intellectual freedom and integrity by avoiding either governmental or any lay control over medical freedom.

THE LAWYER'S BARK AND THE DOCTOR'S BITE

Even a worm will turn, and even a browbeaten doctor on the witness stand will sometimes give a neat back-thrust at the lawyer who bullies him too far. A physician who is telling stories in *Radiology* about his experiences in court recalls an amusing tilt he had a few years ago. He is Dr. I. S. Trostler, of Chicago, and he tells us that the attorney in the case was an old acquaintance, a very large man and known to be extremely abusive to opposing witnesses. Our acquaintance, says Dr. Trostler, did not prevent his applying some of his severest abuse to me.

He had asked me some question to which I had replied, "I do not know," at which he pretended to become very much incensed. Roaring loudly at me, he shook his long index finger under my nose, so close that I could feel the wind stirred up by it; he continued in his apparent attempt to embarrass and browbeat me.

Unabashed and not at all afraid, I stood this for quite a while. Then I gently pushed his hand away from in front of my face and quietly but distinctly said, "Mr. O'D. . . . , if you do not take your finger away from under my nose, I will bite it."

My remark and the accompanying action caused all present to shout with laughter and somewhat startled the big, blustering lawyer. After the bailiff had restored order, I said, "On second consideration, Mr. O'D. . . . , I do not believe that I will bite your finger. It is too dirty," which again caused those present to be convulsed with laughter.

I was excused and the court declared a recess. The big lawyer affectionately put his arm across my shoulder and we walked out together. He assured me that he had never been so disconcerted in his life and he told the story as a good joke on himself several times in my presence.

Correspondence

LOUIS H. PINK
Superintendent of Insurance

STATE OF NEW YORK
INSURANCE DEPARTMENT
ALBANY

October 4, 1935

New York State Journal of Medicine,
33 West 42 Street
New York City.

Dear Sirs:

This Department has been and is the recipient of innumerable complaints and inquiries concerning certain unauthorized insurance companies doing or seeking to do business in this State through the medium of advertisements and solicitation either by mail or through direct personal contact.

Most of these companies have been found unreliable and untrustworthy and have been refused licenses to operate in this State. Doing business with any one of them is at assured's own risk. Not one of them is financially responsible in this State as compared with the fact that life, health and casualty corporations, to secure a license to carry on business in this State must have a minimum of \$100,000.00 in securities required by law on deposit with the Superintendent of Insurance "to be held in trust for the benefit and protection of and as security for the policyholders of the corporation." (Insurance Law, Section 71.)

A few of these unauthorized insurers appear at this time to be carrying on a campaign concentrated on the medical pro-

fession and no doubt have in many instances been successful in placing such policies with uninformed persons, the lure held out being in general, the offer of additional benefits under the policy proffered which cannot, it is claimed, be had by insuring in local companies.

Whether or not this be true and granting the doubt, the advantage of any increased benefit or privilege under such policy would be more than overbalanced by the impotency of assured to force settlement in any situation where a dispute might arise, the assured in such case being absolutely without recourse in this State.

This letter is written with the thought that the subject is of sufficient importance and interest to warrant your estimable publication, through an article or editorial, in issuing a warning to members of the profession against taking out policies of any nature underwritten by such illegally operating concerns.

The doctor is in a position likewise to advise for their protection such patients as appear for examination in connection with life or health policies of insurance, that it be ascertained whether the underwriter is authorized to carry on business in this State.

The enclosed form letter sets forth a few of the dangers of such an investment.

Thanking you in advance for your kind cooperation in the premises, I am

Very truly yours,
JOSEPH E. DEUTSCHBEIN,
Law Case Investigator.

THE NATIONAL FORMULARY, SIXTH EDITION

The American Pharmaceutical Association announces that its Council has officially approved December 16, 1935, as the date when the new N.F. VI will be released for sale in all parts of the country, and has also approved June 1, 1936, as the date when the N.F. VI will become official and will supersede the N.F. V.

As previously announced, the N.F. VI will be distributed for the Association by the Mack Printing Company of Easton, Penna.

The new National Formulary represents a complete and thorough revision of N.F. V. Admissions and deletions are based on information obtained in the U.S.P.N.F. Prescription Ingredient Survey. This survey

was made to determine the materials prescribed and the extent of their use throughout the country. The N.F. VI, therefore, supplements the scope of the Pharmacopoeia and supplies additional information on samples, formulas, diagnostic reagents and standards required by the pharmacist in the practice of his profession.

Of the 689 monographs in the N.F. VI, 208 are Drug or Chemical Monographs and 481 are Monographs of Pharmaceutical Preparations. The more important additions have been in the monographs for ampuls, tablets, fluidextracts, syrups, tinctures and ointments.

Society Activities

Committee on Workmen's Compensation

The following correspondence between the Committee, the Compensation Medical Registrar, and Mr James U Norris President of the Hospital Association of New York State is published here as indicating the status of hospital bills in compensation cases

November 14, 1935

Mr Hugh J Murphy, Compensation Medical Registrar
Department of Labor, State of New York
150 Leonard Street
New York City
Dear Mr Murphy

Rule No 10 promulgated by the Industrial Council prohibits the hospital from collecting medical fees We are creditably informed that the hospitals are continuing to collect and retain fees as formerly and this is being done largely upon the interpretation of a communication addressed by you to Mr James U Norris President of the Hospital Association of New York State, on August 26, 1935

If you will address a second communication to Mr Norris as President of the Hospital Association of New York State, advising him of Rule No 10 and giving him specific instructions to so communicate to all of the institutions of the Association it will go far toward clearing up this matter

If we may have a copy of this second communication we shall see that it is properly circulated to the institutions concerned in the care of injured workmen

Very cordially yours
COMMITTEE ON WORKMEN'S
COMPENSATION

Charles Gordon Heyd, M D
Chairman

David J Kaliski, M D
Frederic E Elliott M D

November 19, 1935

Dr David J Kaliski
Committee on Workmen's Compensation
Medical Society of the State of New York
2 East 103rd Street,
New York City
Dear Doctor Kaliski

In compliance with your communication of the 14th inst, I am enclosing herewith copy of communication sent to Mr James U Norris President of the Hospital Association of New

York State with reference to the manner in which hospital bills should be submitted

Yours very truly

COMPENSATION MEDICAL REGIS-
TRATION UNIT

(Signed) Hugh J Murphy
Compensation Medical Registrar

November 19 1935

Mr James U Norris President
Hospital Association of New York State
141 West 109th Street
New York City
Dear Mr Norris

It has come to my attention that various hospitals are submitting bills to employers and insurance carriers which contain charges for medical and surgical care which of course, is not in accordance with the letter of the law

I was wondering as to whether or not an incorrect interpretation was arrived at by some of these hospitals in my letter to you dated August 26 1935 which you circularized among the hospitals

It is therefore suggested that you again circularize all the institutions of your association advising them as follows

There is no need or necessity for any rules or regulations to be promulgated by the Industrial Commissioner prohibiting hospitals submitting bills which include medical and surgical care as this is very clearly pointed out in Section 13 F, subdivision 1 of the new Medical Practice Act as follows

Hospitals shall not be entitled to receive the remunerations paid to physicians on their staff for medical and surgical services"

It is therefore suggested that you issue instructions to all hospital members of your association that any bills submitted by them should contain charges for general hospital services only

Yours very truly

COMPENSATION MEDICAL REGISTRATION UNIT
Hugh J Murphy
Compensation Medical Registrar

Physicians are invited to refer to the Workmen's Compensation Committee of the Medical Society of the State of New York 2 East 103rd Street, any instances of violation of either the spirit or letter of the above regulation

Medical News

New York County

DR. MAX EINHORN was the guest of honor November 19 at a dinner at the Hotel Astor to celebrate the fiftieth anniversary of his connection with the Lenox Hill Hospital. Dr. Einhorn, who will be 74 in January, recently donated to the hospital the site for a clinic for the study and treatment of cases in the gastroenterological field. About 200 physicians attended the dinner, which was given by the board of trustees, the medical board and the Alumni Association of the Lenox Hill Hospital.

FRIENDS OF Dr. Nathan Ratnoff, medical director of Beth Israel Hospital and Jewish Maternity Hospital, announced at the Waldorf-Astoria at a dinner in honor of his 60th birthday on November 12 that a \$315,000 fund had been raised for assistance of charitable projects which Dr. Ratnoff aided for years.

It was said that the greater portion of the fund would go to Hebrew University in Palestine for use in establishment of a medical department, and to the loan and relief committee of the Medical Society of the County of New York, which controls a fund for relief of physicians in distress.

Sponsors of the dinner, attended by 830 guests, had considered a birthday present to Dr. Ratnoff, but he declined to accept a gift, suggesting that if his friends wished to honor him he would be pleased if they would aid the various works which he had supported.

A WORK WORTH CONTINUING

A timely opportunity to tell what the statewide relief nursing service has done is afforded by its transfer from the State TERA to the WPA. This does not mean any change in organization or conduct. It will continue under the supervision of the State Department of Health. We are told that since its inauguration as a work relief project, the statewide bedside nursing service has provided care to more than 550,000 families, with considerably in excess of a million and a quarter home visits. Of these visits, 568,000 have been for the specific purpose of giving bedside care to the needy sick. The remaining visits were for health instruction and care of special groups; 300,000 to infants and preschool children; 175,000 to school children; 60,000 prenatal and 70,000 postpartum visits; assistance with 3000 confinements in the home and more than 100,000 visits in the interests of controlling tuberculosis, venereal and other communicable diseases.

THE LONG AND BITTER feud between Dr. Menas S. Gregory, former head of the psychiatric division of the Department of Hospitals, and Dr. S. S. Goldwater, Commissioner of Hospitals, has been brought to an end by the withdrawal of a \$250,000 libel suit brought by Dr. Gregory in June, 1934, and his return, as consultant psychiatrist of the psychiatric division of Bellevue Hospital, to the institution which he served for more than thirty years until his resignation eighteen months ago.

The differences between the two men, the subject of acrimonious disputes ever since Dr. Gregory was accused of having shown favors to "wealthy and politically powerful patients" by the Commissioner of Hospitals, were reported to have been settled amicably.

The post of director of the division, from which Dr. Gregory resigned, is still unfilled. Friends of the two men were given credit for having cleared up the misunderstanding which led to the dispute. On November 8, Dr. Gregory had applied to the Supreme Court for permission to ask Dr. Goldwater to specify the persons to whom he was alleged to have shown favoritism while he was at Bellevue Hospital.

The announcement of the understanding was issued by Charles B. Brophy, of 15 Broad Street, counsel for Dr. Goldwater, and by Louis J. Vorhaus, of House, Grossman & Vorhaus, 521 Fifth Avenue, counsel for Dr. Gregory.

In addition these nurses have assisted in 32,488 clinics with an aggregate attendance of 984,271 persons, special emphasis having been given to diphtheria immunization of preschool children, child hygiene and prenatal care. Special nursing for those acutely ill in their homes has been provided for more than 2000 patients.

The marked appreciation of this supplementary service in communities in which it has been rendered demonstrates strikingly the widespread urgent need for additional service which, prior to the inauguration of the relief nursing project, it had been impossible to provide. Every agency equipped and qualified to supervise the work of these nurses has been utilized fully with excellent results. A major objective of this program is to aid in bringing about the establishment of permanent nursing facilities, especially in areas suffering from severe economic distress which will meet more adequately the local needs.

Medical News

Bronx County

THE SOCIAL SEASON of the Bronx County Medical Society is advertised to open "with a BANG," with "delicious food," "heavenly dance music," and "unique and unexcelled entertainment" for "members, their ladies, and friends," on Tuesday, Dec 17, at the Cotton Club, 142d St and Lenox Ave. The proceeds are to go to the relief fund.

THAT THE COST of medical care is felt even by the medical profession is evidenced in the inaugural address of Dr Milton J. Goodfriend, President of the Bronx County Medical Society. "Sickness," he said, "has always been the cause of much distress and financial hardship with a physician and his family. Insurance at present is high and inadequate. We have made preliminary studies and we feel that it is possible to obtain a group insurance plan at low cost to properly protect our members. A committee has been appointed and would like to have your reaction."

A NOTABLE special meeting of the Bronx County Medical Society was held on Nov 25 at Elsmere Hall. The members listened to notable addresses by three distinguished guests: Dr Frederic C. Sondern, President of the New York State Medical Society, Dr James S. McLester, President of the American Medical Association, and Dr J. Fate Mason, President-elect of the American Medical Association.

Cortland County

"VITAMIN B may spell the doom of pink elephants," is the colorful phrase used by a local paper in reporting the address of Dr Peter G. Denker of New York City before the Cortland County Medical Society at the Cortland County Hospital on Nov 15. Lack of Vitamin B, the speaker said, rather than the effects of alcohol, has been found in experiments to cause delirium tremens. Persons drinking heavily, he said, as a rule do not receive sufficient nourishment and fail to get enough of vitamin B in their systems. Experiments show that supplying this vitamin has prevented cases of delirium tremens. Discussion of this subject came up in the course of the doctor's lecture on "Diseases of the Spinal Cord and Peripheral Nerves."

Delaware County

"CAN RIPLEY beat this?" asks the *Downton News*. "Dr O. Q. Flint of Delhi called on Dr Brittain Tuesday afternoon. He made a report on Winfield Lacey, whom

Dr Brittain sent to the Welfare Hospital at Delhi on Thursday, Oct 31, for an operation for intestinal obstruction. Dr. Latcher of Oneonta operated and found an obstruction, the cause of which, after close examination, proved to be a porcupine quill about three fourths of an inch in length. It is presumed that this had entered the body somewhere and finally lodged in the intestines. The patient is doing well."

Erie County

THE "MERCY DEATH" plea of a Buffalo woman, played up sensationally by the daily press is now regarded as a hoax or a stunt inspired by a more or less energetic newspaper reporter. Her plea for death was supposedly addressed to the Erie County Medical Society, but the secretary says that no such communication has been received. She was injured in an automobile accident more than two years ago and members of her family are quoted as saying that her injuries were slight and that she has now practically recovered. Her physician is reported as attributing her statement to "overwrought nerves caused by pain and brooding." Meantime acres of newsprint have been defaced by interviews with almost everyone willing to talk on the good old topic of euthanasia.

IT WAS VOTED unanimously at the meeting of the Erie County Medical Society on Nov 18 to name a committee to study the desirability of having a publicity representative to handle news matters and correct mistaken reports about the profession.

At the same meeting candidates for offices were nominated as follows: President, Dr Milton Potter and Dr John L. Eckel, first vice president Dr John T. Donovan, second vice president Dr Thurber Le Win and Dr Harry C. Guess, secretary, Dr Louise W. Beams, treasurer, Dr Caryl A. Koch, board of censors, Health Commissioner Francis E. Fronczak, Dr Charles W. Bethune, Dr Abraham Weil, Dr F. J. Rutlak and Dr M. A. Sullivan.

For the chairmanship of the committee on public health, Dr Joseph O'Gorman, chairman of economics, Dr John Hoffman and chairman of the committee on membership, Dr C. A. Bentz. For the post of delegate, eight to be selected, Dr Bauckus, Dr Mary Kazmierczak, Dr O'Gorman, Dr Charles Leone, Dr Marshall Clinton, Dr Albert Gartner, Dr Matthew Carden, Dr Harvey P. Hoffman and Dr John S. Grun-Franceschi. Chairman of Legislation, Dr James L. Gillighey.

Fulton County

DR. LLOYD ZIEGLER of Albany was the principal speaker at the meeting of the Medical Society of Fulton County on Nov. 20 in Gloversville. He read a paper on "Practical Psychopathology."

Kings County

THE FOLLOWING new officers were nominated on Nov. 19 by the Kings County Medical Society at its monthly meeting in MacNaughton Auditorium, 1313 Bedford Ave.: Dr. Henry Jochim, president; Dr. Thomas A. McGolderick, president-elect; Dr. John B. D'Albora, vice president; Dr. Joseph Rafael, secretary; Dr. Thomas B. Wood, associate secretary; Dr. Augustus Harris, treasurer; Dr. John McCabe, associate treasurer; Dr. Jacques C. Rushmore, librarian, and Dr. Edwin P. Maynard, Jr., associate librarian.

The Alumni Association of St. Catherine's Hospital presented a portrait of Dr. Frank Dormer Jennings to the society. The portrait was accepted by Dr. Edwin P. Maynard, Jr., the curator.

Dr. Walter Bauer, assistant professor of medicine at Harvard, gave an illustrated lecture on arthritis. At the business meeting following Dr. Bauer's paper, the society went on record as favoring medical supervision of industrial laboratories.

Monroe County

WARNING HAS BEEN received by the Medical Society of Monroe County of three so-called "human test tubes" who may attempt to dupe the Rochester public with a fake exhibit, posing as under sponsorship of the Mayo Clinic, Rockefeller Foundation and American Medical Association. The group allege they are demonstrating experiments in diet, sleep and locomotion and appear exclusively on roller-skates. The report says that although they put on a good roller-skating show, their connection with the medical clinics has been denied and likewise the validity of their scientific "experiments."

Queens County

DR. THOMAS CLARK CHALMERS, of Forest Hills, died on November 16 at Exeter, N. H. He was 67.

Dr. Chalmers was active in organized medicine and for many years was a delegate of the New York State Medical Society to the conventions of the American Medical Association. Many times in conventions he sponsored resolutions calling for modification of the Volstead act. He was in part responsible for the modifica-

tion which permitted physicians to give alcohol to patients.

From 1921 to 1922 he was president of the Queens County Medical Society and chairman of the board from 1924 to 1931. He was chairman of the building committee for the organization's new building at Forest Hills. He was a member of the New York Academy of Medicine and president of the Medical Association of Greater New York in 1927. Dr. Chalmers was also president of the Society of Medical Jurisprudence from 1924 to 1926.

AT A RECENT MEETING of the Queens County Medical Society in the Medical Building, Forest Hills, Dr. James R. Reuling of Bayside was nominated as president-elect.

Dr. Reuling will become president-elect on Jan. 1, succeeding Dr. James Dobbins of Long Island City. Dr. Dobbins will automatically succeed Dr. Morris S. Bender of Jamaica as president Jan. 1.

Others named were Dr. Guernsey Frey of Forest Hills, secretary, and Dr. William Barry of Long Island City, treasurer.

St. Lawrence County

DR. F. F. WILLIAMS was elected president of the St. Lawrence County Medical Society at the annual meeting and dinner on November 21 at Ogdensburg.

Dr. Williams, who has been practicing at Canton for half a century, succeeds Dr. John E. Free of the Hepburn Hospital surgical staff, who has held the office during the past year.

For vice-president the society chose Dr. W. H. Mulholland of Heuvelton. Dr. S. W. Close of Gouverneur was reelected secretary. He has held that office for 48 years. Dr. L. T. McNulty of Norwood was reelected treasurer.

Dr. R. J. Reynolds of Potsdam was chosen delegate to the House of Delegates of the New York State Medical Society, with Dr. S. W. Sayer of Gouverneur as alternate. Drs. C. E. Elkins of Massena and M. J. Stearns and Paul G. Taddiken of Ogdensburg were reelected to the board of censors. A scientific program was presented, the feature of which was an address by Dr. Free on "Surgery in Pulmonary Tuberculosis." Dr. D. M. Brumfield of Saranac Lake read a paper on "Silicosis" and Dr. Homer L. Sampson of Saranac Lake presented a paper on "X-ray Findings in Silicosis." Dr. J. R. Patton, medical director of St. John's Tuberculosis Hospital and S. E. Simpson, superintendent of the Jefferson County Sanitarium, also spoke.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

An Interesting Foreign Body Case

An interesting case* in which a surgeon was exonerated from charges of malpractice came before the Courts of one of the Pacific States recently. The subject matter of the litigation was the leaving of a sponge in the abdominal cavity during an operation. The facts must be set forth at some length to appreciate the ruling in the case.

A woman, forty three years of age, consulted a general practitioner with respect to varied complaints. He called into consultation Dr. D. and the two doctors diagnosed the condition as a pelvic infection requiring operation. Dr. D. therefore, performed an operation upon her with the assistance of the other doctor, and several nurses. Upon opening the abdomen the pelvic organs and the intestines were found grown together in a mass. Both Fallopian tubes were abscessed. The right ovary and tube was a mass of abscesses which according to the surgeon held about a quart of pus, and filled the whole pelvis. The uterus contained numerous fibroid tumors. In the course of dissecting those tumors and the intestines from the broad ligament, the abscess ruptured. In order to clean up the great amount of pus, approximately eight dozen sponges were used of various types. The operation was necessarily a very long and difficult one, taking over two hours in all. Finally the diseased organs were all removed, and the pus had been sponged out, and the sponges removed, and the surgeon started to close the abdomen. At this point one of the nurses suggested that she believed one of the sponges was missing.

What followed from that point on was described by the surgeon as follows:

We always make a mental note when they put a big sponge in, or two big sponges, or three big sponges. I always keep them in my mind and when they are taken out and we were all three confident there was not a sponge left in the abdomen or we did not put any sponges in there. We counted out all the sponges we had put in and were all confident this sponge had not been used, but notwithstanding I opened the wound again and put my hand into the abdomen and felt around and made a hurried examination but did not find any sponge could not feel any sponge or anything abnormal and made the remark that we would have to hurry

up and get this patient off the table and resuscitate her, and so I went on and closed the wound, excepting that we put in drainage.

Well, on account of the condition of the patient, and the length of time that she had been undergoing this operation, the amount of work there was connected with the operation, the patient had been getting in a bad shape, and it was time that she was taken off, the anaesthetic stopped and resuscitation begun.

Q After she had been on the table two hours, and subjected to this heavy operation what was your best judgment whether there could be a sponge there or not, as to whether or not you ought to carry the operation further with regard

A Well it was absolutely essential that we should not carry on any further if there had been a sponge left in there if I had known there was a sponge left in there, I would have left the sponge at that time, if I could not have found it conveniently, I would have left the sponge there temporarily and removed the sponge later.

Q Even if you had known it was there?

A Even if I had known there was a sponge in there. She had undergone a heavy operation when you remove one ovary and both Fallopian Tubes, a large abscess and the womb complete in a case like that and being a couple of hours under the anaesthetic, it is time to get that patient out of there and this patient especially. She was in bad shape. She had stood just about all that she could stand, and it was time to take her out, and it is up to me. It is my business to say whether I shall stop this operation this minute or carry it on one half hour longer or ten minutes longer, and I acted on what I thought was my best judgment in her case, and my judgment told me to stop that operation right then and close up the wound and stop the anaesthetic and put her to bed and resuscitate her.

Undoubtedly a sponge was left in the body of the patient during that operation for about five weeks later the same surgeon made another incision into the patient's abdomen and removed a sponge.

The patient instituted a malpractice action against Dr. D. charging him with negligence in permitting the sponge to remain in her body and claiming that such negligence was the cause of the second operation and the cause of ill health. The defendant conceded that the sponge had been left in after the first operation, but asserted that under the circumstances he had been guilty of no neglect and that the sponge had caused the

*Rayburn v. Day, 268 P. 1002

patient no harm, but that the later operation had become necessary due to the formation of a secondary abscess, an aftermath of the severe pelvic infection.

Upon the trial the defendant's story was substantially as above, and he was corroborated by the nurses and by his assistant. *The plaintiff undertook to establish negligence from the conceded failure to remove the sponge and by testimony concerning conversations with the doctor after the operation, relied upon as admissions of negligence.* There was testimony that established that the sponge would be a means for the propagation of pus.

At the conclusion of the evidence the Court sent the case to the jury and instructed them as to the defendant's liability in part as follows:

I instruct you that the defendant is not liable for a mere error of judgment, if such judgment is based upon the exercise of reasonable care and skill; and in this connection I instruct you that if you find from the evidence that the attention of the defendant, Dr. D. was called to the possibility of the one sponge being short or missing, and if in the exercise of his judgment, he ceased to explore the body of the patient for the sponge, after making such examination as he deemed prudent, if he made such examination, and if you find that the defendant in good faith decided to make no further exploration and search at that time for the reason that he considered such search might endanger the life of the patient, then he had a right to act upon his own judgment, and no negligence could be inferred therefrom, provided he exercised reasonable care and skill. . . . If you find that the defendant exercised his judgment based upon the exercise of reasonable care and skill, if he did, in the matter of his examination of the patient's body to ascertain if all sponges were accounted for, then he was not guilty of negligence, and plaintiff could not recover, but, if he failed to exercise reasonable care and skill, then I instruct you that the defendant would be liable and your verdict should be for the defendant.

The jury returned a verdict in favor of the defendant, and an appeal was taken to the highest State Court by the plaintiff.

The plaintiff as one of the principal grounds for the appeal urged that the Court had improperly charged the jury upon the trial. The plaintiff claimed to have been entitled to certain alternative instructions, which her counsel upon the trial had requested. Those requests to charge, which had been denied included the following:

You are hereby charged that the use of sponges constituted a part of the operation, just as much as the opening of the body with the knife, that the operation begins with the beginning of the opening in the body, and ends when the opening has been closed, and that the use of the sponge during the course of the

operation constituted a part of the operation, and that the proper removal of the sponges from the body was a part of the operation. The removal of the sponge was a part of the operation, and, if the defendant failed to remove the sponge, he left the operation uncompleted so long as the sponge remained within the body of the plaintiff.

The Appellate Court, however, refused to disturb the instructions given to the jury by the trial Court, determining that they were fair and proper, and affirmed the verdict and judgment in favor of the doctor. In so ruling the Court made the following remarks in its opinion:

A failure to remove a sponge would not in all instances constitute a breach of the surgeon's duty to use due care; if such was its essential effect, there was no need to take testimony in this case, because the defendant admitted that he left the sponge in the incision. Yet the concluding portions of each proposed instruction, if given, might have created in the mind of the juror the conception that the defendant owed an absolute duty to remove all sponges, that a sponge left in the incision constituted a breach of that duty. . . . We believe that the Court did not prejudice the plaintiff's rights when it failed to give the foregoing requested instructions.

Death From Removal of Tonsils and Adenoids

A man brought his three year old son to a doctor specializing in ear, nose and throat work and explained to the doctor that the boy was having trouble with his breathing and probably needed an operation.

The doctor examined the boy and found that he was suffering from hypertrophied tonsils and adenoids and suggested their removal.

A few days later the boy was brought to a hospital and an operation was performed upon him, under general anesthesia, and the tonsils were removed by dissection and snare and the bleeding was controlled by ligation and the use of a hemostat. After this the adenoids were removed by means of an adenoid curette and the bleeding following this was controlled by pressure with gauze sponges. All bleeding was stopped before the child was put to bed in the hospital.

The following morning the doctor examined the boy's throat and found it clean and found the child in excellent condition, so he permitted the child's parents to take him home. He never saw the patient again.

The doctor subsequently learned that within a few weeks after the operation the child had died from some sort of lung trouble.

An action was brought against the doctor

by an administrator who was appointed for the child, to recover damages claimed to have been sustained by reason of the boy's death which it was claimed resulted from the negligence of the defendant doctor. The claim was made that the operation itself was negligently performed, and that subsequent thereto the defendant failed to give the child necessary and proper postoperative treatment and that as a result he developed postoperative septicemia and died.

Across the Desk

Gaskets vs. Caskets

IT APPEARS FROM recent investigations that a serious or even fatal automobile accident may be caused by only two parts of carbon monoxide from a motor exhaust in ten thousand parts of air, if breathed for $2\frac{1}{2}$ to 4 hours. Motorists of course have been warned for years about this deadly gas, but few have realized how little it takes to dull the driver's responses, dizzy his brain, and flaw his judgment. Four parts in ten thousand cause collapse and eight are fatal. A little leak in a gasket may let out enough to poison the air in the car and do the trick, and a clever writer suggests that "a new gasket is cheaper than a casket."

But isn't there another danger, one that no amount of new gaskets can help? Our city streets are like trenches, walled-deep with brick and stone, into which hundreds of thousands of motors discharge torrents of exhaust gases all day and every day. Might not the mixture at times amount to two parts in ten thousand, and be sufficient to account for some of the crashes? Carbon monoxide is only slightly lighter than air, four per cent lighter, to be exact, and in the busy part of the day the air in the streets must be more than a little tainted. And what is more, carbon monoxide does its fatal work by displacing the oxygen in the red corpuscles of the blood, and is cumulative in its effect, so that its action is insidious and creeps upon us before we know it. The driver threading his way through crowded traffic is surrounded by motor exhaust pipes pouring out streams of carbon monoxide to right, to left, before and behind. Is it credible to suppose that it has no effect? Something more is needed than a new gasket.

It would be easy to carry this farther, and ask if our twenty million automobiles have not affected all of us more or less with their carbon monoxide infiltration. One effect of the gas is said to be "impaired

When the case was reached for trial in its regular order the case was marked from the calendar by reason of the failure of the plaintiff's attorney to proceed with the case at that time.

Some time later a motion was made dismissing the case for failure on the part of the plaintiff to prosecute the action and at that time the plaintiff stipulated to discontinue the action.

judgment." We certainly have seen plenty of that around in recent years. Some have gone so far as to say that everybody seems to be going crazy. Queer actions unquestionably have been going on, even in Washington, but we must not blame them all on the old car. That would be a little cracked, too.

One thing, at least, could be done that would be in the right direction, anyway. Practically every other kind of exhaust pipe, on our locomotives, steamships, motorships, and factories, discharges upward, away from everyone, while the automobile discharges its exhaust almost in the face of people in the street. It would be simplicity itself to lead the pipe inconspicuously to a high point at the rear and send the gases upward. Then the CO, a little lighter than air, aided by its heat and the push of the exhaust, would rise to harmless levels. Some trucks already have arrangements of this kind which look home-made, perhaps installed to protect the men while loading and unloading, but at any rate it shows what native common sense can do when applied to the problem.

Kidding Captain Kidd

UNSCRUPULOUS DRUG DEALERS are now outdoing themselves. They make Captain Kidd seem like an amateur and will be able to kid him unmercifully if they meet him in some future life sailing the lakes of molten brimstone. They are "more active than ever before," according to no less an authority than the Chief of the Food and Drug Administration at Washington. Their latest game is to buy up old and deteriorated products in "salvage" sales and "distressed merchandise" transactions and work them off on the public. Seizures have brought the discovery of goods that have actually been on the shelves since before the Food and Drug Law was enacted. In Texas alone the State and Federal officers seized and destroyed 28 tons of these dangerous old

patient no harm, but that the later operation had become necessary due to the formation of a secondary abscess, an aftermath of the severe pelvic infection.

Upon the trial the defendant's story was substantially as above, and he was corroborated by the nurses and by his assistant. The plaintiff undertook to establish negligence from the conceded failure to remove the sponge and by testimony concerning conversations with the doctor after the operation, relied upon as admissions of negligence. There was testimony that established that the sponge would be a means for the propagation of pus.

At the conclusion of the evidence the Court sent the case to the jury and instructed them as to the defendant's liability in part as follows:

I instruct you that the defendant is not liable for a mere error of judgment, if such judgment is based upon the exercise of reasonable care and skill; and in this connection I instruct you that if you find from the evidence that the attention of the defendant, Dr. D. was called to the possibility of the one sponge being short or missing, and if in the exercise of his judgment, he ceased to explore the body of the patient for the sponge, after making such examination as he deemed prudent, if he made such examination, and if you find that the defendant in good faith decided to make no further exploration and search at that time for the reason that he considered such search might endanger the life of the patient, then he had a right to act upon his own judgment, and no negligence could be inferred therefrom, provided he exercised reasonable care and skill. . . . If you find that the defendant exercised his judgment based upon the exercise of reasonable care and skill, if he did, in the matter of his examination of the patient's body to ascertain if all sponges were accounted for, then he was not guilty of negligence, and plaintiff could not recover, but, if he failed to exercise reasonable care and skill, then I instruct you that the defendant would be liable and your verdict should be for the defendant.

The jury returned a verdict in favor of the defendant, and an appeal was taken to the highest State Court by the plaintiff.

The plaintiff as one of the principal grounds for the appeal urged that the Court had improperly charged the jury upon the trial. The plaintiff claimed to have been entitled to certain alternative instructions, which her counsel upon the trial had requested. Those requests to charge, which had been denied included the following:

You are hereby charged that the use of sponges constituted a part of the operation, just as much as the opening of the body with the knife, that the operation begins with the beginning of the opening in the body, and ends when the opening has been closed, and that the use of the sponge during the course of the

operation constituted a part of the operation, and that the proper removal of the sponges from the body was a part of the operation. The removal of the sponge was a part of the operation, and, if the defendant failed to remove the sponge, he left the operation uncompleted so long as the sponge remained within the body of the plaintiff.

The Appellate Court, however, refused to disturb the instructions given to the jury by the trial Court, determining that they were fair and proper, and affirmed the verdict and judgment in favor of the doctor. In so ruling the Court made the following remarks in its opinion:

A failure to remove a sponge would not in all instances constitute a breach of the surgeon's duty to use due care; if such was its essential effect, there was no need to take testimony in this case, because the defendant admitted that he left the sponge in the incision. Yet the concluding portions of each proposed instruction, if given, might have created in the mind of the juror the conception that the defendant owed an absolute duty to remove all sponges, that a sponge left in the incision constituted a breach of that duty. . . . We believe that the Court did not prejudice the plaintiff's rights when it failed to give the foregoing requested instructions.

Death From Removal of Tonsils and Adenoids

Kidding Captain Kidd

UNSCRUPULOUS DRUG DEALERS are now outdoing themselves. They make Captain Kidd seem like an amateur and will be able to kid him unmercifully if they meet him in some future life sailing the lakes of molten brimstone. They are "more active than ever before," according to no less an authority than the Chief of the Food and Drug Administration at Washington. Their latest game is to buy up old and deteriorated products in "salvage" sales and "distressed merchandise" transactions and work them off on the public. Seizures have brought the discovery of goods that have actually been on the shelves since before the Food and Drug Law was enacted. In Texas alone the State and Federal officers seized and destroyed 28 tons of these dangerous old

stocks. In one drug store in Dallas the officers seized 13 antiquated medicinals obtained through foreclosure, bankruptcy, auction or other distress sales, claiming to benefit stomach troubles, women's disorders, rheumatism, eczema, boils, whooping cough, croup, ringworm, catarrh, hay fever, ulcerated sore throat, dandruff, tonsilitis, pyorrhea, piles, bone abscess, kidney and bladder troubles, quinsy, bronchitis, consumption, dropsy, blood diseases, tumors, cancer, nervous ailments, or what-have-you. The proprietor was fined \$400. He was modest, however, compared with a suave druggist in Butler, Ind., who was found selling a "salt" for 53 diseases, including ulcers, cancer, Bright's disease, tuberculosis, scarlet fever and diphtheria. This agile character pleaded guilty unexpectedly and slipped by with a fine of \$1. We ought to hear more of him.

This shows in a brief and vivid flash what the honest and conscientious druggist is up against in the way of piratical and cut-throat competition. It gives the reason why the doctor should throw his influence to the man who keeps character and honor behind his prescriptions. The chemist is passing through a crisis that tests every moral fiber, and it is to the interest of sound medicine to help him maintain the best and highest standards. Some of the leading pharmacists of New York City, united in the Retail Druggists Association, are now working on a Code of Professional Practices. They have appointed a committee to work with the medical profession "toward educating the lay public to the value of the independently owned drug store and the individual practicing physician." Their first step will be "to revitalize their prescription departments" and cooperate more closely with the physician. If the doctors and druggists can unite to help the federal and state officers rout out the scalawags and blacklegs who are preying murderously on the sick and ignorant poor, they will deserve well of the republic.

Surveys—Suspicious and Auspicious

SUSPICIONS ARE BEING expressed in various quarters that the medical survey now on in 19 states will be used to help the drive for state medicine in the coming session of Congress. "It is understood," says the *A.M.A. Journal*, "that the stimulus for this survey came from the Secretary of Labor, and that it meets with Administration approval." There can hardly be any doubt that it will reveal many thousands of sick people who are not receiving medical care. This survey, however, may well be welcomed by the medical profession. In

fact, the Medical Association of Georgia called for such a survey in its own state at two annual meetings and is now working hand in hand with the state and federal health authorities in making the canvass. Once the survey is completed, its findings can be used just as well by organized medicine to further some good plan as by the visionary socializers to boost a bad one. Dr. Paullin, President of the Georgia state body, says that the survey "should accumulate data which will be of inestimable value to the Medical Association of Georgia in helping to perform its needed function of rendering adequate medical care to all of the people." The President of the Wisconsin State Medical Society, too, believes that if the survey is made and reported thoroughly and impartially, "much valuable information which has hitherto been lacking may be secured, and this information may help a great deal in the solution of many of our medical-economic problems." Some program like the Detroit Plan or the Atlanta Plan that is acceptable to the medical profession, could be advanced to meet the situation as revealed.

Not Too Many Doctors

THE IDEA that there are too many doctors is pretty likely to be shattered with the finding that large numbers of sick people are without medical care and that large areas are without proper preventive measures against such diseases as smallpox, diphtheria and typhoid. There are not too many doctors, but too few. The trouble, as the President of the Kentucky State Medical Association points out, is that they are not properly distributed. His state made a survey a few years ago which found that the cities are gradually acquiring a surplus while the smaller towns and rural communities are suffering a constantly increasing scarcity. Young doctors coming from the medical schools cannot afford to go into the rural regions where incomes are problematical. If some method could be found to adjust the maldistribution it ought to provide a living for every doctor now on relief or in distress, and mitigate the evils and abuses of free clinics and the charity list. The immunization needs of the country, alone, would give work to our total imaginary "surplus" of physicians.

Just a glimpse of what could be done can be had by turning the eye to Michigan, where the State Medical Society has joined forces with the State Hospital Association and the Probate Judges Association to give medical care to crippled and afflicted children. The action was precipitated by a crisis in the financial affairs of the Crippled Chil-

dren's Commission, but it was an ill wind which blew much good, we are told, for out of chaos came order, and the physician took his proper place in medical planning for the state. Now the county medical society will cooperate with local probate judges and hospitals in medical care for crippled children and the doctor will have due recognition and compensation. The time seems to be at hand all along the line for organized medicine to make a stand for recognition in all matters pertaining to the care of the sick.

One of the first lessons of military

strategy is that it is not enough merely to beat the enemy. He must be pursued, broken up, cut to pieces, beyond all chance of a reorganization and a new attack. The medical forces fought off the foe with great gallantry last winter and spring. That was only a starter, just enough to warm up. Now a new battle is in prospect, based on the national health survey. This time the tactics should be not only to halt the socializers and visionaries, but to capture their trenches, machine guns and artillery and make any counter attack impossible.

Books

REVIEWED

A Textbook of Surgery For Students and Physicians. By W. Wayne Babcock, M.D. Second edition, revised. Quarto of 1312 pages illustrated. Philadelphia, W. B. Saunders Co., 1934. Cloth, \$10.00.

This is the very welcome second edition of a surgical textbook the first edition of which, published in 1928, has proven to be an excellent text for students and practitioners. The general plan of the earlier edition has been followed.

The great advances which surgery has been making since 1928 has made it necessary to revise and rewrite practically all of the chapters. New sections have been added on the parathyroid glands, the sympathetic nervous system, the duodenum, the mesentery and omentum, the epiphyses and the malacias of bone. New illustrations have been uniformly excellent.

This second edition brings the subject matter well up to date. As in the earlier edition, the presentation is very clear and concise. The surgical field has been thoroughly covered with proper emphasis upon the points of greater importance.

The author is to be congratulated for his excellent accomplishment which is worthy of unqualified recommendation.

EDWARD P. DUNN

The Brain as an Organ. Its Postmortem Study and Interpretation. By Frederic Wertham, M.D. & Florence Wertham. Octavo of 538 pages illustrated. New York, The Macmillan Company, 1934. Cloth \$7.50.

In the face of the several monographs and textbooks of neurology and neurohistology which have appeared in this country during the past year, the publication of another work is itself a mark of courage. It needs but superficial inspection to convince one that the present book packs not only courage, but a punch in its origin.

It is so far removed from the unnecessary stodginess of treatises in this field that one values the purely technical chapters all the more.

The unconventional character which distinguishes this book on the pathological study of the brain is due to the fact that it attempts to transmit ideas rather than interminable and tedious techniques. The modernism of the Werthams is the point of view which calls for a dynamic approach to brain problems instead of fixating them in the hardening fluid of 19th century descriptiveness.

The fruitful sections of the book are the chapters on the individual histological syndromes, on comparative histopathology, the critique of the problem of dementia precox and the chapter on forensic neurohistology. The section on general paresis develops the Wertham's thesis that most so called well defined histological syndromes are not really so. They base their conclusions on their findings that similar pictures are developed in animal encephalitis, etc. This section admirably presents the notion of heterogeneity in neurology, but the choice of general paresis is unfortunate since the authors fail sufficiently to take the mental side of the picture into account. The psychiatry of the parietic is one of the oldest and best founded pictures in all of medical history. The histological picture is practically as characteristic as the psychiatric one. The practical ends are not greatly assisted by dragging in the spontaneous encephalitis of chickens, which can hardly ever demonstrate the parietic psychiatric picture for us, regardless of the duplication of brain lesions.

The chapter on dementia precox should be helpful in laying the ghost of the "organic" in this turbulent field. The use of the concept 'organic' as applied to

schizophrenia need not postulate demonstrable cell changes in the brain. Allergy is an organic concept not less than bone, but no one calls upon the allergists to produce the histological pictures. The constitutional evidences of disease should be sufficient unto the term. The Wertham's exposition of histological failure in this direction is worth every psychiatrist's and neurologist's careful study.

The chapter on forensic neurohistology is little more than a fillip. The physical properties of the book frame the contents excellently, but we could wish that the authors would, in their next edition, expunge most of their unsupported assertions in the purely technical sections or display the evidence. It seems to be essentially a fault of their style of writing, which is otherwise exemplary.

SAM PARKER

X-Ray Interpretation. By H. Cecil H. Bull, M.D. Octavo of 382 pages, illustrated. New York, Oxford University Press, 1935. Cloth, \$7.00.

There are many books and monographs written on the subject of Radiology, many stress a special branch thereof, but this book is rather all comprehensive in 370 pages and therefore is of general use to the clinician rather than outstanding in original thought or depth of knowledge on any particular branch of the subject. It is written in easy, simple style and directs the practitioner in logical sequence upon the radiographic appearance in health and disease.

Its great value is the prominence given the normal, since without it, as the author states in his preface, "no accurate conception of the pathological is possible."

Line drawings and silhouettes are employed to illustrate, but unusual as it may seem, no X-ray photographs appear. Pathology is therefore well expressed didactically, but we fear the absence of the X-rays themselves is a glaring want.

For one with some knowledge of the subject, much can be learned from the text and illustrations, and to those desirous of a working knowledge of the specialty, it becomes a handy reference.

MILTON G. WASCH

The Nervous Patient. A Frontier of Internal Medicine. By Charles P. Emerson, M.D. Octavo of 453 pages. Philadelphia, J. B. Lippincott Co., 1935. Cloth, \$4.00.

While this book is neither fish nor fowl, it is in many respects a highly palatable dish. The author himself calls his work a "frontier of internal medicine," regarding all neurotic ills as somehow rooted in or-

ganic disturbances, and most organic diseases as largely dominated by nervous mechanisms. It is true that, if you wait long enough, even neurotics are going to die from tuberculosis, cancer and heart disease. But it is sophistical to imply that these diseases should have been suspected or discovered behind the nervousness. The continued emphasis which the book lays on the human inter-relationship between organic and psychic influences is refreshing and valuable, coming from a responsible internist.

The book is dedicated to the practitioner and it is clear that the general physician may find the greatest profit in it. The arrangement of the material is decidedly unconventional and adjusted to fit problems and minor questions as they are likely to arise in the busy practitioner's experience. There is no rigid attempt to line the wealth of modern research detail up in literary fashion. The arrangement of the chapters makes the work a handy and practical reference of sensible proportions. An inspection of details, such as therapeutic suggestions or theoretical backgrounds, reveals the author as eminently sane and devoid of frills.

The first half of the book covers practically all of internal medicine in concise chapters which contain no interminable discussions. These sections serve best to bring one's understanding of problems up to date. The remainder of the book is given over to problems with which the practitioner is daily faced, but never reads about in his texts: marriage, all kinds of named and un-named neuroses, birth-control, diseases of the brain, eugenics, etc. While these sections are not for the neuropsychiatrist, they are well done for this type of book.

SAM PARKER

A Synopsis of Medicine. By Henry Letheby Tidy, M.D. Sixth edition, Revised and enlarged. Duodecimo of 1112 pages. Baltimore, William Wood & Co., 1934. Cloth, \$6.00.

This is a concise and inclusive review of a system of medicine. The general arrangement of the text follows that of Osler's "Principles and Practice of Medicine," but is necessarily written in a very abbreviated style. The new edition has undergone extensive changes, especially in the sections devoted to Diseases of Deficiency, Endocrinology and Diseases of the Bones. The book provides an excellent reference for hasty reviews of almost any subject in internal medicine, but of course, it will not replace a standard textbook of medicine.
